#### 4 Abstract

5 Background: *CHD8* haploinsufficiency causes autism and macrocephaly with high
6 penetrance in the human population. *Chd8* heterozygous mice exhibit relatively subtle brain
7 overgrowth and little gene expression changes in the embryonic neocortex. The purpose of this
8 study was to generate new, sub-haploinsufficient *Chd8* mouse models to allow us to identify
9 and study the functions of CHD8 during embryonic cortical development.

Methods: To examine the possibility that certain phenotypes may only appear at subheterozygous *Chd8* levels in the mouse, we created an allelic series of *Chd8*-deficient mice to reduce CHD8 protein levels to approximately 35% (mild hypomorph), 10% (severe hypomorph) and 0% (neural-specific conditional knockout) of wildtype levels. We used RNA sequencing to compare transcriptional dysregulation, structural MRI and brain weight to investigate effects on brain size, and cell proliferation, differentiation and apoptosis markers in immunostaining assays to quantify changes in neural progenitor fate.

17 Results: Mild Chd8 hypomorphs displayed significant postnatal lethality, with surviving 18 animals exhibiting more pronounced brain hyperplasia than heterozygotes. Over 2000 genes 19 were dysregulated in mild hypomorphs, including autism-associated neurodevelopmental and 20 cell cycle genes. We identify increased proliferation of non-ventricular zone TBR2+ 21 intermediate progenitors as one potential cause of brain hyperplasia in these mutants. Severe 22 *Chd8* hypomorphs displayed even greater transcriptional dysregulation, including evidence for 23 p53 pathway dysregulation. In contrast to mild hypomorphs, these mice displayed reduced 24 brain size and increased apoptosis in the embryonic neocortex. Homozygous, conditional 1 deletion of *Chd8* in early neuronal progenitors resulted in pronounced brain hypoplasia, partly 2 caused by pronounced p53 target gene derepression and apoptosis in the embryonic neocortex. 3 Limitations: Our findings identify an important role for the autism-associated factor CHD8 in 4 controlling the proliferation of intermediate progenitors in the mouse neocortex. We propose 5 that CHD8 has a similar function in human brain development, but studies on human cells are 6 required to confirm this. Because many of our mouse mutants with reduced CHD8 function die 7 shortly after birth, it is not possible to fully determine to what extent reduced CHD8 function 8 results in autism-associated behaviours in mice.

9 **Conclusions:** Together, these findings identify important, dosage-sensitive functions for 10 CHD8 in p53 pathway repression, neurodevelopmental gene expression and neural progenitor 11 fate in the embryonic neocortex. We conclude that brain development is acutely sensitive to 12 reduced CHD8 expression and that the varying sensitivities of different progenitor populations 13 and cellular processes to CHD8 dosage result in non-linear effects on gene transcription and 14 brain growth.

16

17

#### 1 Background

Mutations in *CHD8* (Chromodomain helicase DNA-binding protein 8) are some of the highest
confidence risk factors for autism spectrum disorder (ASD) identified to date (1-5), with 96%
of individuals with *CHD8* mutations presenting with autism, and 64% with macrocephaly (6,
7).

6

7 CHD8 encodes a member of the ATP-dependent CHD chromatin remodelling family (8) and 8 was initially identified as a direct repressor of  $\beta$ -catenin and p53 target genes (9-12). Early 9 embryonic lethality of homozygous Chd8 deletion in the mouse is associated with p53-10 mediated apoptosis, consistent with its role as a transcriptional repressor of p53 target genes 11 (11). By contrast, CHD8 is typically recruited to promoters enriched for transcriptionally-12 permissive chromatin marks in neural progenitors, suggesting a role for CHD8 in 13 transcriptional activation (13, 14). Indeed, ASD-associated genes were downregulated in 14 neural progenitor cells upon CHD8 knockdown (13, 14). Evidence for mild brain overgrowth, 15 reminiscent of the macrocephaly observed in patients with CHD8 mutations, has been reported 16 in several different Chd8 heterozygous mouse models (15-18) Jimenez ref.

17

To explore the transcriptional dysregulation that may underlie abnormal brain development in heterozygous mice, gene expression has been investigated at different stages of brain development. These studies have revealed subtle gene expression changes in *Chd8*<sup>+/-</sup> mice during embryonic development (15, 17-19). By contrast, in vitro studies on neural progenitor cells have identified more substantial transcriptional dysregulation arising from CHD8 knockdown. For instance, Sugathan et al. observed 1756 differentially expressed genes (DEGs) upon *CHD8* knock-down in human iPSC-derived neural progenitor cells (14). Gene expression changes in *Chd8<sup>+/-</sup>* mice also appear to be strongly influenced by developmental stage, with
 more extensive transcriptional changes observed at peri- and postnatal stages (17, 18).

3

4 The striking phenotypes associated with human CHD8 mutations and pronounced gene 5 expression changes in neural progenitor cell lines upon CHD8 knockdown, contrast with the 6 mild brain and embryonic transcriptional abnormalities observed in Chd8 heterozygous mice. 7 The only study so far to report convincing ASD-like behavioural phenotypes associated with 8 Chd8 deficiency, involved Chd8 knock-down to ~20% of wildtype protein levels by selective 9 in utero electroporation of neuronal progenitors contributing to upper layer neurons (20). 10 Together, these findings suggest that CHD8 haploinsufficiency may have more pronounced 11 effects on human brain development, or that some human ASD-associated mutations may 12 reduce CHD8 function by more than 50%.

13

14 To examine the possibility that certain phenotypes may only appear at sub-heterozygous Chd8 levels in the mouse, we created an allelic series of Chd8-deficient mice to reduce CHD8 protein 15 16 gradually to approximately 35% (mild hypomorph), 10% (severe hypomorph) and 0% 17 (conditional knockout) of wildtype levels. Non-monotonic effects on brain growth were 18 observed, with mild hypomorphs exhibiting increased brain size, and severe hypomorphs and 19 conditional knockout mice smaller brain size. We found that increased brain size in mild 20 hypomorphs was associated with increased proliferation of TBR2+ intermediate progenitors. 21 As this cell type contributes to increased human brain expansion during evolution (21), this 22 finding suggests that CHD8 may have more pronounced effects on human brain development. 23 We conclude that reducing CHD8 function below 50% have disproportionally large, and non-24 linear effects on gene expression and brain development.

#### 1 Methods

2

#### 3 Animals

4 A transgenic mouse line containing a *Chd8<sup>neo</sup>* allele (*Chd8<sup>tm1.Mabn</sup>*) was generated as reported 5 previously (18). Briefly, an 18.8 kb targeting construct was generated consisting of a 14.84kb 6 genomic DNA fragment subcloned from a C57BL/6 BAC clone (RP23:318M20) with an added 7 loxP/FRT-PGK-gb2-Neo cassette 3' of exon 3 (ingenious Targeting Laboratory (iTL), 8 Ronkonkoma, NY, USA) and additional loxP site 5' of exon 3 (Fig. 1). The targeting construct 9 was linearised and electroporated in C57BL/6J ES cells. Five clones were identified with 10 successful recombination, two of which (124 and 254) were injected into Balb/c blastocysts. 11 Resulting chimaeras were backcrossed onto a C57BL/6J background to generate Chd8neo/+ mice. Experimental Chd8neo/neo mice were produced by Chd8neo/+ x Chd8neo/+ crosses. To 12 generate a conditional *Chd8* allele (*Chd8<sup>flox</sup>* (*Chd8<sup>tm1.1Mabn</sup>*)), *Chd8<sup>neo/+</sup>* mice were crossed with 13 Flpe deleter mice on a C57BL/6J background (Fig. 1). Chd8<sup>flox/+</sup> mice were then either inter-14 15 crossed to obtain a homozygous Chd8<sup>flox/flox</sup> line or with Sox1-Cre (22) to generate Sox1-Cre; Chd8<sup>flox/+</sup> mice. To produce pan-neuronal Chd8 null (conditional knockout, cKO) mice, Sox1-16 Cre: Chd8<sup>flox/+</sup> mice were mated with Chd8<sup>flox/flox</sup> mice. Sox1-Cre: Chd8<sup>flox/flox</sup> cKO embryos 17 were compared with Sox1-Cre; Chd8<sup>flox/+</sup> (cHET) and Chd8<sup>flox/flox</sup> (Ctrl) embryos. To generate 18 conditional p53-heterozygotes, mice carrying the  $Trp53^{tm1Brn}$  conditional ( $p53^{flox}$ ) allele were 19 20 obtained from the Jackson laboratories (23) and crossed to the Chd8 conditional mice. Chd8<sup>flox/+</sup> mice were also bred with  $\beta$ -actinCre mice (24) to generate a Chd8 null (Chd8<sup>-</sup>, 21 (*Chd8<sup>tm1.2Mabn</sup>*)) allele.  $\beta$ -actinCre; Chd8<sup>+/-</sup> mice were then crossed with C57BL/6J mice to 22 remove the Cre transgene and establish a  $Chd8^{+/-}$  line.  $Chd8^{+/-}$  mice were produced by  $Chd8^{+/-}$ 23 24 x C57BL/6J crosses, taking care to equalise paternal or maternal inheritance of the Chd8 null allele. Experimental Chd8neo/- mice were produced by Chd8neo/+ x Chd8+/- crosses. In 25

experiments comparing different genotypes, replicate samples were from different litters to
 avoid litter-specific effects. All animal procedures were approved by the UK Home Office.

3

#### 4 Genotyping of mice

5 Genomic DNA was extracted for genotyping from ear samples (or yolk sac for embryos aged 6 E14.5 and below) using Proteinase K digestion or the HotSHOT method (25). Genotyping 7 reactions were then performed for the presence of Chd8 wildtype, null or floxed alleles, p53 8 wildtype or floxed alleles, as well as the presence of Cre. Thermal cycles for all genotyping 9 reactions were as follows: 94°C, 5 minutes; 35X (94°C, 30sec; 58°C, 30sec; 72°C, 30sec); 72°C, 5 minutes. Primer pairs to amplify a sequence distinguishing between Chd8<sup>flox</sup>, Chd8<sup>neo</sup> and 10 11 wildtype alleles ('Chd8flox' primers, 212bp and 275bp product for mutant or wildtype, 12 respectively), to detect the presence of the Chd8null allele ('Chd8null' primers, 395bp), to 13 distinguish between p53 floxed and wildtype alleles ('p53flox' primers, 390bps and 270bps, 14 respectively) and primers to amplify a specific Cre sequence ('Cre' primers, 390bp product) 15 were used as listed in Suppl. Table 5.

16

#### 17 RNA extraction and qRT-PCR analysis

18 Cortical RNA was extracted by lysing cortices in 600µl Trizol (Life Technologies). After 19 purification, RNA was DNase treated using the Direct-zol RNA MiniPrep kit (Zymo Research) 20 according to the manufacturer's recommendations. cDNA was synthesised for qRT-PCR 21 experiments using 50ng RNA from 4 biological replicates per condition with the Precision 22 nanoScript 2 Reverse Transcription Kit (PrimerDesign Ltd.) according to the manufacturer's 23 instructions. qRT-PCRs were performed on a Stratagene Mx3000p (Agilent Technologies) 24 using PrecisionPlus-MX 2x qPCR Mastermix with SYBR green (PrimerDesign Ltd.) and 25 primers against Atm, Atr, Trp53, Cdkn1a, Ccng1, Mdm2, Chd8, and Pmaip1. Relative 1 expression levels were calculated using the  $2^{-\Delta\Delta C_T}$  method and *Gapdh* and *Ywhaz* were used as 2 endogenous control genes.

3

#### 4 Western blot

5 Telencephalic vesicles were dissected from E12.5 embryos and whole cell protein prepared by 6 lysing in 8M urea, 1% CHAPS, 50mM Tris (pH 7.9) lysis buffer containing protease inhibitors 7 (PMSF, Pepstatin A, Leupeptin, Aprotinin; Roche) and a phosphatase inhibitor cocktail 8 (Sigma). After rotating at 4°C for 30 mins, DNA was removed from lysates by centrifugation. 9 Supernatant was transferred to a fresh tube and stored at -80°C. Protein loading samples were 10 made by diluting samples in Laemmli buffer containing 10% β-mercaptoethanol, followed by 11 boiling at 100°C for 10 minutes. Samples were loaded (10µg total protein per lane) onto a 12 Mini-PROTEAN pre-cast gel (Bio-Rad) and resolved using gel electrophoresis. Protein was 13 transferred to a nitrocellulose membrane (Bio-Rad), which was then blocked in 5% non-fat 14 milk powder (Bio-Rad) and 1% bovine serum albumin (BSA, Sigma) in TBS with 0.1% 15 Tween-20 (TBST) for one hour at room temperature. Where  $\beta$ -actin was used as a loading 16 control, the membrane was then cut in two: the higher molecular weight section was incubated 17 with anti-CHD8 primary antibody (rabbit anti-CHD8 N-terminal, Bethyl Laboratories, 1/2000) 18 and the lower molecular weight section incubated with anti- $\beta$ -actin antibody (rabbit anti- $\beta$ -19 actin, Abcam, 1/4000); both antibodies in 3% non-fat milk powder and 1% BSA in TBST 20 overnight at 4°C. After washing, membrane was incubated with HRP-conjugated secondary 21 antibody (Millipore) for one hour at room temperature. HRP was detected with Clarity ECL 22 reagent (Bio-Rad) and the membrane imaged using a Bio-Rad ChemiDoc system. Where 23 GAPDH was used as a loading control, the uncut membrane was washed in TBST after 24 detection of CHD8 protein and incubated overnight at 4°C in 0.05% sodium azide in PBS, 25 before washing and incubation with anti-GAPDH primary antibody (rabbit anti-GAPDH,

Abcam, 1/40000) overnight at 4°C. Membrane was probed with HRP-conjugate and imaged as before. Raw proteins levels were quantified using Bio-Rad ImageLab software. All replicates on each given blot were first normalised to their respective GAPDH loading controls. Where the same samples were run across multiple blots their normalised values were averaged across all blots and this value used for statistical analysis. Normalised values for all samples were compared by ANOVA to identify statistically significant differences between the different genotypes.

8

#### 9 Structural MRI

10 Mice were terminally anaesthetised and intracardially perfused as described previously (18). 11 Voxelwise comparisons were made between mutants and all wildtypes taken from both the 12  $Chd8^{+/-}$  and  $Chd8^{neo/neo}$  batches. As wildtype brain sizes differed slightly between the two 13 groups due to slightly different age at analysis,  $Chd8^{neo/neo}$  data were first normalised (beta-14 corrected) to wildtypes in the  $Chd8^{+/-}$  batch before analysis. Voxelwise comparisons were then 15 made between mutants and all wildtypes, and multiple comparisons in this study were 16 controlled for using the False Discovery Rate (26).

17

#### 18 Behavioural assessments

Mice for behavioural testing were maintained as described previously (18). Housing and test rooms were kept at constant temperature (21°C) and humidity (45%) and maintained under a regular light/dark schedule with lights on from 07:30 to 19:30 hours (light = 270 lux). All mice used in behavioural assessments were housed and tested at the same facility at King's College London.

24

25 Different batches of *Chd8<sup>neo/neo</sup>* mice were used for (i) recording pup ultrasonic vocalisations

1 (USVs) and spontaneous movements, followed by tests for adult behaviours and (ii and iii) 2 adult behaviours. For the first *Chd8<sup>neo/neo</sup>* batch (i), tests were carried out in the following order: 3 ultrasonic vocalisations (P2-P12), self-grooming (8-10 weeks), open field (9-11 weeks), adult 4 social investigation (9-11 weeks), three-chamber social approach (9-11 weeks) and olfactory 5 habituation/dishabituation (10-12 weeks). For the other two batches (ii and iii), tests were 6 carried out as follows: rotarod (8-10 weeks), self-grooming (9-11 weeks), open field (10-12 7 weeks), adult social investigation (10-12 weeks), marble burying (11-13 weeks), 3 chamber 8 social approach (11-13 weeks) and olfactory habituation/dishabituation (12-14 weeks). The 9 final batch was then further assessed using the running-wheel test (16-20 weeks). Data from 10 different batches did not differ significantly and were all combined for analysis.

11

12 One week before performing the rotarod test, mice were singly-housed to avoid any potential 13 confounds from social and aggressive behaviour hierarchies, which could influence the 14 controlled assessment of social behaviours (27). Sawdust was changed every other week but 15 never on the day before, or the day of testing. The enrichment (nesting material and house) was 16 changed less regularly to minimize the disruption to the animals. For all social tests, conspecific 17 mice were housed in a separate room to the test mice to ensure the conspecifics were unfamiliar 18 to the test mice. Test mice were never exposed to the same conspecific during testing to ensure 19 novelty.

20

Behavioural experiments were conducted between 08:30 and 18:30 in sound-proofed rooms under standard room lighting unless stated otherwise. Behaviours were recorded using a camera positioned above the test arenas and movement of each mouse tracked using EthoVision (Noldus Information Technologies, by Wageningen, The Netherlands). Social investigation, olfaction and grooming were scored manually using MATLAB 2016b (The

MathWorks, Inc., Natick, Massachusetts, USA). After each individual trial of a specific test,
 boli and urine were removed from the test arena which was cleaned with 1% Anistel® solution
 (high level surface disinfectant, Trisel Solution Ltd, Cambridgeshire, UK) to remove any odors.
 Experimenters were blind to the genotype of the animals both during the testing and subsequent
 scoring of the recorded behaviours.

6

#### 7 RNA Sequencing

8 For RNA-sequencing at E10.5, total RNA from 2 embryos was pooled for each biological 9 replicate (n=3 per condition). No pooling was performed at E12.5 (n=3 per condition). mRNA 10 was isolated and reverse transcribed into cDNA. cDNA was end-repaired, adaptor-ligated and 11 A-tailed. Paired-end sequencing (75bp read length) was performed on the Illumina HiSeq 4000 12 platform. Quality of the raw sequencing data was checked using FastQC version 0.11.2 and 13 trimming of adaptor sequences was performed using Trim Galore! version 0.4.1 (28). Reads 14 were aligned to the mouse genome (GRCm38.p4) using Tophat version 2.1.0 and aligned reads 15 were counted using FeatureCounts version 1.5.0 (29, 30). Differential expression testing was 16 performed using DESeq2 version 1.10.1, as previously described (31). Gene ontology analysis 17 and functional classification was performed using DAVID with all detected DEGs below a 18 0.05FDR (32). For heatmaps, data were transformed with a variance stabilising transformation, 19 scaled and clustered with the Ward.d2 method using maximum distance, and plotted with the 20 R package pheatmap version 1.0.8. The R package ggplot2 version 2.1.0 was used to generate 21 volcano plots and DESeq2 was used to generate normalised read count plots for individual 22 genes. The list of ASD associated genes used for overlap with the neo/neo DEGs was obtained 23 from the SFARI Human Gene database (https://gene.sfari.org/autdb/HG Home.do). RNA-seq data have been deposited into GEO, accession number GSE81103. 24

#### 1 Tissue collection and processing

2 Embryos were collected and brains dissected from the skulls in ice-cold PBS for E18.5 3 embryos. Wholemount pictures were taken on a Nikon SMZ1500 stereomicroscope equipped 4 with a Nikon DS-Fi1 camera head, followed by post-fixation in 4% PFA for 24h at 4°C. For 5 BrdU experiments, pregnant mothers (day 13 or 15 of gestation) were injected with 40mg/kg 6 BrdU in 0.9% saline 1 hour prior to embryo collection. After fixing, embryos were dehydrated 7 and paraffin embedded. Paraffin blocks were then cut into 10µm (cKO and cKO;p53-het embryos) or 5µm (Chd8<sup>+/-</sup>, Chd8<sup>neo/neo</sup> and Chd8<sup>neo/-</sup> embryos) thick coronal sections and 8 9 mounted.

10

#### 11 X-gal staining

E9.5 embryos were collected and dissected in ice-cold PBS and post-fixed in 4% PFA for 10 minutes. Following three washes in PBS (5 minutes each), embryos were incubated in X-Gal staining solution (10mM TRIS-HCL, pH7.3, 0.005% Na-deoxycholate, 0.01% IGEPAL, 5mM potassium ferrocyanide, 5mM potassium ferricyanide, 2mM MgCl<sub>2</sub>, 0.8mg/ml X-Gal, in PBS) at room temperature until adequate signal was observed. Reactions were stopped by washing in PBS (3 x 5 minutes) followed by post-fixation in 4% PFA for 1h. Control embryos never showed any staining.

19

#### 20 Immunohistochemistry and Immunofluorescence

Coronal brain sections were re-hydrated using standard protocols. Antigen retrieval was conducted by heating slides in 10mM Sodium Citrate solution (pH6) for 20mins and cooled on ice. For non-fluorescence immunohistochemistry, endogenous peroxidases were blocked by incubating in 3% H<sub>2</sub>O<sub>2</sub> and 10% MeOH in PBS for 15mins. Sections were then washed in 0.2% Triton X-100 (Sigma-Aldrich) in PBS (PBT2) for 5 mins and blocked using 10% heat-

1 inactivated normal goat serum (GS) and 2% gelatin in PBT2 for 1 hour. Sections were 2 incubated in 5% GS in PBT2 containing primary antibody overnight at 4°C. The following 3 antibodies were used: mouse anti-BrdU (BD Biosciences, 1/100), rabbit anti-phosphohistone 4 3B (Cell Signaling, 1/100), mouse anti-phosphohistone 3B (Abcam, 1/200), chicken anti-5 TBR2 (Merck Millipore, 1/200), rabbit anti-cleaved-caspase 3 (Cell Signaling, 1/200), rabbit 6 anti-doublecortin (Abcam, 1/400) or rabbit anti-CHD8 (Bethyl, 225A, 1/400). For 7 immunofluorescence, sections were incubated with secondary antibody diluted in 5% GS in 8 PBT2 for 90mins at 4°C. Secondary antibodies used included goat anti-chicken AlexaFluor 9 488 (Invitrogen, 1/200), goat anti-mouse AlexaFluor 405 (Invitrogen, 1/200), goat anti-mouse 10 AlexaFluor 594 (Invitrogen, 1/200), goat anti-rabbit AlexaFluor 488 (Invitrogen 1/200), goat 11 anti-rabbit AlexFluor 568 (Invitrogen, 1/200) and donkey anti-rabbit AlexaFluor 488 12 (Invitrogen, 1/200). Sections were counterstained using Hoechst 33342 solution (Invitrogen, 13 1/50,000) in PBS and covered with coverslips using CitiFluor (CitiFluor Ltd., UK). For 14 diaminobenzidine (DAB) immunohistochemistry, after incubation with primary antibody, 15 sections were incubated in biotinylated anti-rabbit immunoglobulin secondary antibody (Dako, 16 1/200) in 5% GS in PBT2. Samples were washed in PBS and incubated with Avidin/biotin 17 complex (ABC, Vector) in PBS for 1 hour. Sections were developed using 0.03% DAB and 0.0003% H<sub>2</sub>O<sub>2</sub> in PBS for 10mins before washing in running water and counterstaining using 18 19 Ehrlich's Haemotoxylin solution. Slides were mounted onto coverslips using DPX (Sigma-20 Aldrich). Images were acquired on a Nikon 80i microscope equipped with a Hamamatsu C4742 21 CCD or Nikon 5M pixel Nikon DS digital cameras. Images were processed using Adobe 22 Photoshop and Illustrator.

23

#### 24 Fluorescence-activated cell sorting (FACS) and qRT-PCR

25 Pregnant females were sacrificed by cervical dislocation on embryonic day 14.5 (E14.5) and

1 embryos were dissected out and placed in ice cold Hibernate-E solution supplemented with 2 B27. The brain was dissected out from each embryo and the cortex removed. Cortices were maintained in ice-cold Hibernate-E/B27 whilst embryos were genotyped after which cortices 3 4 with corresponding genotypes were pooled together in digest solution (0.25% Trypsin, 0.01% 5 DNase, 10 mM HEPES in HBSS) preheated to 37°C. Cortices were incubated in digest solution 6 for 10 minutes and washed in HBSS + 0.01% DNase to inactivate trypsin. Single-cell 7 suspension was achieved through mechanical dissociation by gentle pipetting. Cells were 8 washed and resuspended with PBS, incubated on ice and in the dark for 30 minutes with 1 µl 9 of the near-IR fluorescent reactive dye from the LIVE/DEAD fixable dead cell stain kit 10 ThermoFisher). Cells were washed once with PBS, strained into fixing solution (1.6% PFA 11 and 0.1% saponin in molecular-grade PBS) supplemented with 1% RNasin Plus RNAse 12 inhibitor and incubated on ice for 30 mins. Cells were washed twice with wash solution (0.2% 13 BSA, 0.1% saponin, 0.1% RNasin Plus in molecular-grade PBS) before antibody staining. The 14 following primary antibodies were used: phycoerythrin (PE)-conjugated mouse anti-PAX6 (sc-15 81649, Santa Cruz Biotechnology) and chicken anti-TBR2 (AB15894, Merck Millipore). Cells 16 were suspended in staining solution (1% BSA, 0.1% saponin, 1% RNasin Plus in molecular-17 grade PBS) containing primary antibodies at a 1:1000 dilution and incubated on ice for 30 18 minutes. Cells were washed twice with wash solution then suspended in staining solution 19 containing anti-chicken AlexaFluor 488 secondary antibody (A-11039, ThermoFisher) at a 20 1:1000 dilution. Cells were washed twice with wash solution then strained and resuspended in 21 sorting buffer (3% BSA and 2 mM EDTA in molecular grade PBS). Fluorescence-activated 22 cell sorting (FACS) was performed using a FACSAria III machine (BD). Samples stained 23 individually for TBR2 and PAX6 were used as compensation controls. Debris was excluded 24 from samples by gating on a forward and side scatter area plot and doublets excluded by gating 25 on a plot of side scatter area by side scatter width. The LIVE/DEAD marker was detected in

1 the APC-Cy7 channel. Any cells showing greater fluorescence intensity than an unstained 2 control sample were considered dead and excluded. The unstained sample was also used to set 3 a double negative gate on a PE by FITC fluorescence intensity plot. The PAX6+ gate was 4 placed based on increased PE fluorescence and the TBR2+ gate placed based on increased 5 FITC fluorescence. Selection gates were placed towards the extreme ends of the cell population 6 to ensure the sorting of single positive cells only. Cells falling within the PAX6+ or TBR2+ 7 gates were sorted and collected in sorting buffer. Cells were then pelleted, snap frozen in liquid 8 nitrogen and stored at -80°C. RNA was extracted from sorted cell samples using the RecoverAll 9 Total Nucleic Acid isolation kit (Life technologies) using the RNA isolation protocol with an 10 adapted protease treatment for 3 hours at 50°C to maximise RNA yield. RNA concentration 11 was determined with a NanoDrop 2000 (ThermoFisher). Typically, samples yielded 12 approximately 120 ng of RNA which was stored at -80°C. Reverse transcription was performed 13 using the Precision nanoScript2 Reverse Transcription Kit (Primerdesign) according to the 14 manufacturer's instructions using random nonamer primers. 60 ng of RNA was reverse 15 transcribed for all samples and resulting complementary DNA (cDNA) stored at -20°C. qPCRs 16 were performed using Luna Universal qPCR Master Mix (New England Biolabs). Samples of 17 3.75 ng cDNA were run in triplicate for each primer pair using a Lightcycler 480 (Roche) and fold expression changes were calculated using the  $2^{-\Delta\Delta CT}$  method. Primer sequences are given 18 19 in Suppl. Table 5.

20

#### 21 Quantification and statistical analysis

#### 22 General

Data are reported as Mean±SEM and graphs show all individual data points where feasible.
Significant p-values are reported in the results section and figure legends provide details of
relevant statistical parameters, including group sizes. Statistical analyses were performed either

with SPSS (Version 22, IBM, Armonk, USA) or GraphPad Prism (Version 6, GraphPad
 Software, La Jolla, California, USA). All analyses were performed blind to genotype.

3 RNAseq

4 Processing of raw data and differential expression testing is described in the methods section.
5 Multiple comparisons were controlled for using an FDR<0.05. Exact p-values and FDR</li>
6 adjusted p-values for all differentially expressed genes are listed in Supplementary Tables 3 &
7 5.

#### 8 Cell marker quantification

#### 9 **Proliferation**

10 Proliferation was quantified by counting either ventricular or non-ventricular phosphohistone 11 3B-positive cells and normalising cel counts to the length of ventricular surface. Cells were 12 counted in sections located between A-P positions 219-236 of the E14.5 Allen brain reference 13 atlas for coronal sections (https://developingmouse.brain-14 map.org/experiment/thumbnails/100074513?image type=hp yellow) and from the boundary 15 with the eminences up to the "apex" of the neocortex in the M-L axis. Normalised counts were 16 averaged across both hemispheres for at least three sections to give the number of 17 phosphohistone 3B-positive cells per µm of ventricular surface in the dorsal cortex of each 18 embryo. To determine the molecular identity of non-ventricular PH3B+ cells at E14.5, sections 19 were co-stained for TBR2 and the number of TBR2/PH3B double-positive cells counted and 20 normalised to ventricular surface length.

21

#### 22 Apoptosis

Cleaved Caspase 3 (CC3) positive cells were counted in the E14.5 neocortex and normalised
to ventricular zone length in each hemisphere as described above. Counts were averaged across

1 both hemispheres and across a minimum of three sections per biological replicate. In E12.5 2 cKO embryos, CC3-positive cells were counted in 50µm x 50µm boxes. Three boxes were 3 counted for both inner (ventricular side) and outer (pial side) regions of the dorsal cortex to generate an average number of CC3-positive cells per  $\mu$ m<sup>2</sup> for both inner and outer cortical 4 5 regions, which were then averaged to provide the overall mean of CC3-positive cells per  $\mu m^2$ . 6 These were calculated for both sides of the brain individually in at least two sections per 7 biological replicate. Apoptosis in the ventral cortex was quantified by counting CC3+ cells 8 either in three 0.1mm x 0.1mm boxes in both lateral ganglionic eminences and three 0.15mm 9 x 0.15mm boxes in both medial ganglionic eminences (WT and cHet), or three 0.1mm x 0.1mm 10 boxes placed at equivalent positions across the ventral cortex (cKO and cKO-p53Het) and 11 counts averaged for each section. These were calculated for both sides of the brain individually 12 in at least two sections per biological replicate.

13

#### 14 **Data availability**

15 The RNAseq raw data and read counts were deposited at the Gene Expression Omnibus (GEO)16 archive under the accession number GSE121381.

17

#### 1 **Results**

#### 2 A Chd8 allelic series reveals non-linear effects of CHD8 deficiency on brain growth.

3 To establish a *Chd8* allelic series in the mouse, we first generated a hypomorphic *Chd8* allele 4 (Chd8<sup>neo</sup>, Fig. 1A) by inserting a neo cassette between exons 3 and 4 to reduce gene expression 5 through splicing and termination of transcripts (33, 34). Aberrant splicing of Chd8 transcripts into the neo cassette was confirmed (Fig. 1A). Chd8neo/neo and Chd8neo/- embryos showed 85% 6 7 and 88% reductions in Chd8 transcripts, respectively, compared to the 63% decrease in Chd8<sup>+/-</sup> 8 embryos (Fig. 1B). Full-length CHD8 protein levels were reduced by approximately 50% in 9 Chd8<sup>+/-</sup>(heterozygous), 64% in Chd8<sup>neo/neo</sup> (mild hypomorph), and 91% in Chd8<sup>neo/-</sup> (severe 10 hypomorph) neocortices, with no evidence for remaining truncated CHD8 protein products 11 (Fig. 1C, Suppl. Fig. 1).

12

*Chd8<sup>neo/neo</sup>* mice exhibited a significant reduction in postnatal survival (Table 1). As CHD8 is
 expressed in multiple tissues during development (35), this postnatal lethality is likely a
 consequence of congenital defects affecting essential organs.

16

18

17	Table 1: Reduced	postnatal	survival of	Chd8neo/neo	<sup>o</sup> pups.
----	------------------	-----------	-------------	-------------	--------------------

	Births	P0	P14***	P35***	expected %
Chd8 <sup>neo/neo</sup>	24.7	16.2	8.1	8.2	25
Chd8 <sup>neo/+</sup>	51.7	56.8	59	55.7	50
<i>Chd8</i> <sup>+/+</sup>	23.6	27	32.8	36.1	25
	n=89	n=74	n=271	n=97	

19 Mice were born at expected Mendelian frequencies from *Chd8<sup>neo/+</sup>* intercrosses. Percentage

survival is shown for the different genotypes at P0, P14 and P35. Note the significantly reduced observed percentage of homozygous *Chd8<sup>neo/neo</sup>* mutants at P14 and P35 (\*\*\*p<0.001, Chi-

observed percentage of homozygous *Chd8<sup>neo/neo</sup>* mutants at P14 and P35 (\*\*\*p<0.0</li>
 square test) in two independent groups of mice.

1	High resolution structural MRI revealed volumetric increases in a number of brain regions in
2	Chd8neo/neo mice compared to wildtype littermates (Fig. 1D). This phenotype was more
3	pronounced than in $Chd8^{+/-}$ mice (Fig. 1D), with total brain volume increased by 4.5% in
4	$Chd8^{neo/neo}$ mice, compared to the 2.7% increase in $Chd8^{+/-}$ mice (Fig. 1E). As our $Chd8^{+/-}$ data
5	were from males only, we also calculated the increase in brain volume increase in male
6	$Chd8^{neo/neo}$ mice only, to exclude the possibility that female $Chd8^{neo/neo}$ mice were responsible
7	for the observed increase in brain volume. The average brain volume of <i>Chd8<sup>neo/neo</sup></i> male mice
8	(n=8) were increased by 5.4% compared to their male wildtype littermates (n=14), compared
9	to the 2.7% increase in volume of male $Chd8^{+/-}$ mice (n=12) compared to their male wildtype
10	littermates (n=12). Several regions that showed evidence of overgrowth in $Chd\delta^{+/-}$ mice (Fig.
11	1E, Table 2) demonstrated robust increases in volume in <i>Chd8<sup>neo/neo</sup></i> mice, including the frontal,
12	cingulate and entorhinal cortices and the hippocampus (Fig. 1E, Table 2, Suppl. Table 1).
1.0	

#### Table 2. Brain volume differences relative to control wildtype littermates

	Chd8 genotype	
Brain area	+/-	neo/neo
brain volume	2.73%	4.53%**
cortex	3.82% -	5.53%**
cerebellum	3.41%	6.99%**
hippocampus	5.97% -	5.84%**
primary motor cortex	3.68% -	6.68%**
primary somatosensory cortex	3.7% -	5.62%**
primary auditory cortex	3.2%	6.23%**
primary visual cortex	3.39%	7.15%**
frontal cortex	3.99% -	5.21%**
frontal association cortex	4.81% -	6.07%**
entorhinal cortex	4.83% -	7.05%**
cingulate cortex	4.57% -	4.84%**
amygdala	3.82%	4.64%*

-FDR<0.15; \* FDR<0.05; \*\*FDR<0.01. MRI data from  $Chd8^{+/-}$  and littermate control mice used for comparison are from Suetterlin et al. (18). 

1 To determine the effects of reducing Chd8 levels further, we assessed postnatal survival of *Chd8<sup>neo/-</sup>* severe hypomorphs. *Chd8<sup>+/-</sup>* x *Chd8<sup>neo/+</sup>* matings yielded no live *Chd8<sup>neo/-</sup>* animals by 2 3 P7-P14 (n=0/22), indicative of a significant postnatal lethality (p<0.001; Chi-square test). To 4 assess the phenotype of severe hypomorphs, we collected embryos at E18.5. Measuring brain weights in these embryos, revealed that Chd8neo- brains were 13.4mg (18.3%) lighter than 5 brains from Chd8<sup>+/+</sup> littermates (Suppl. Fig. 2A,B,E,G). Chd8<sup>+/-</sup> brains weighed on average 6 7 4.74mg (6.47%) heavier than controls (Suppl. Fig. Fig. 2C,D,F,G), in agreement with our 8 previous report (Suetterlin et al, 2018). In addition, 50% of Chd8neo/- embryos showed 9 unilateral anopthalmia (Suppl. Fig. 2H), in agreement with strong Chd8 expression in the 10 developing eye (35). Taken together, these data suggested that brain growth responds to 11 reductions in CHD8 levels in a non-linear manner, with heterozygotes and mild hypomorphs 12 exhibiting brain overgrowth, and severe hypomorphs presenting with brain hypoplasia.

13

# 14 *Chd8*<sup>neo/neo</sup> mice demonstrate mild behavioural anomalies similar to those seen in *Chd8*<sup>+/-</sup> 15 mice.

To explore whether behavioural phenotypes may be exacerbated in the Chd8neo/neo mild 16 hypomorphs compared to  $Chd8^{+/-}$  mice, we assessed socio-communicative, repetitive, anxiety 17 18 and motor behaviours. In total, three batches of Chd8neo/neo mice were assessed for the same 19 behaviours. As no batch effects and no sexually dimorphic behaviours were observed, data 20 from all three experiments and both sexes were combined for analysis. Chd8 hypomorphs 21 displayed normal social approach and investigation behaviours in the three-chamber (Fig. 2A) 22 and reciprocal social investigation tests (Fig. 2B). Relative to wildtype littermates, hypomorph 23 pups emitted normal numbers of ultrasonic vocalisations (USVs) on separation from the nest, 24 suggesting no deficits in socio-communicative abilities (Fig. 2C). Furthermore, Chd8neo/neo 25 mice demonstrated a normal capacity for habituation and dishabituation to both social (sex-

1 matched urine) and non-social (banana) odours (Fig. 2D). We did not observe any differences 2 in repetitive self-grooming behaviour between hypomorphs and wildtypes (Fig. 2E). In the 3 marble burying test, a task also designed to measure repetitive behaviours in mice, Chd8neo/neo 4 mice buried fewer marbles than controls (Fig. 2F). Interestingly, Chd8 hypomorphs showed 5 increased aversion towards the centre of the open field arena (Fig. 2G-H), suggesting that 6 reduced Chd8 expression may predispose to anxiety. In addition, these mice demonstrated 7 decreased locomotor activity in the open field arena, even when controlling for their anxiety 8 phenotype (Fig. 2I). This hypo-active phenotype was corroborated by homecage running wheel 9 tests (Fig. 2J) and may account for the reduced marble burying observed in these mice. 10 However, the hypo-activity did not appear to be due to motor defects, as these mice showed 11 motor performance comparable to controls in the rotarod test (Fig. 2K).

12

13 In summary, Chd8neo/neo mice showed no evidence of socio-communicative deficits or 14 repetitive behaviours typically associated with ASD, suggesting that the reason for a lack of 15 robust ASD-like behaviours in Chd8-deficient mouse models is unlikely to be an insufficient 16 reduction in Chd8 expression. The most robust, reproducible phenotype was locomotor hypoactivity, which was present in both our mild hypomorphic and  $Chd8^{+/-}$  mice (18), and also 17  $Chd8^{+/-}$  mice reported by Platt et al. (16). Intriguingly, whereas our  $Chd8^{+/-}$  mice did not show 18 19 clear anxiety phenotypes (18), the Chd8 hypomorphs did, suggesting that this particular 20 phenotype may be enhanced by a reduction in *Chd8* levels.

21

# Gradual reductions in CHD8 levels result in progressively more pronounced gene expression changes.

To understand how sub-heterozygous *Chd8* levels affect gene expression in the embryonic
 neocortex, RNA-sequencing (RNA-seq) was performed from E12.5 neocortices. Data from

heterozygous (*Chd8<sup>+/-</sup>*), mild (*Chd8<sup>neo/neo</sup>*) and severe (*Chd8<sup>neo/-</sup>*) hypomorphs, together with
 their respective wildtype littermate controls were included for analysis.

3

4 This analysis identified only 14 differentially expressed genes (DEGs, excluding Chd8, FDR <0.05) in Chd8<sup>+/-</sup> (Fig. 3A, Suppl. Table 2, Suppl. Fig. 3) and 2209 DEGs in Chd8<sup>neo/neo</sup> 5 6 neocortices (Fig. 3B, Suppl. Table 2, Suppl. Fig. 3), indicating that many genes only show 7 significant transcriptional effects when CHD8 levels fall below 50%. In Chd8neo/- embryos, 8 2592 DEGs (FDR <0.05) were identified (Fig. 3C, Suppl. Table 2, Suppl. Fig. 3). The 9 visualisation of differential gene expression in a heat map demonstrated the marked 10 transcriptomic differences between heterozygotes and mild hypomorphs (Fig. 3D). DEGs 11 could be divided into four groups based on their responses to reduced CHD8 levels: 1) genes 12 that show a "linear" response to *Chd8* downregulation (e.g. *Tet1* and *Zcwpw1*, Fig. 3E, Suppl. Fig. 3C), 2) genes that are not significantly different in  $Chd8^{+/-}$  embryos but sharply up- or 13 downregulated in Chd8neo/neo embryos (e.g. Nlgn3 and Slc1a5, Fig. 3E, see also Suppl. Fig. 3B), 14 15 3) genes that are only significantly dysregulated in *Chd8<sup>neo/-</sup>* embryos (e.g. *Gpat2*), and 4) genes that exhibited non-linear responses (e.g. Slc9b2, Fig. 3E). The majority of DEGs (>99%) fell 16 17 within group 2, indicating that over 2000 genes showed a striking threshold response as CHD8 18 protein is reduced from heterozygotes to mild hypomorphs.

19

Comparing DEGs in *Chd8<sup>neo/neo</sup>* and *Chd8<sup>neo/-</sup>* samples identified 1389 genes common to both datasets (Fig. 3F), all of which were changed in the same direction. ASD-associated genes were highly enriched in the DEGs from both *Chd8<sup>neo/neo</sup>* (145 genes, p=1.32x10<sup>-9</sup>, OR = 1.83, Fisher's exact test for count data, Fig. 3F, Suppl. Table 2) and *Chd8<sup>neo/-</sup>* embryos (152 genes, p= 5.532 x10<sup>-7</sup>, OR = 1.62, Fisher's exact test for count data, Suppl. Table 2). Nearly half (46%) of these ASD-associated genes were common to *Chd8<sup>neo/neo</sup>* and *Chd8<sup>neo/-</sup>* mice (Fig. 26%).

3F). The majority (89% and 88%, respectively) of ASD-associated DEGs were downregulated
 (orange and red fractions in Fig. 3G, Suppl. Table 2), supporting the idea of CHD8 as an
 important positive regulator of neurodevelopmental, autism-associated genes (13, 14).

4

5 To determine if CHD8 functions as a positive or negative regulator of gene expression, we 6 identified genes most likely directly regulated by CHD8, using ChIP-seq data from Cotney et 7 al. (13). From the Cotney dataset, a consensus set of gene promoters with CHD8 recruitment 8 in E17.5 embryonic mouse brain, human midfetal cortex, and neural progenitor contexts was 9 defined. This gene list was compared to the list of differentially expressed genes in Chd8 10 hypomorphs. This analysis revealed that the majority of DEGs were not identified in the 11 consensus CHD8 ChIP-seq dataset (blue and orange fractions in Fig. 3G), suggesting that most 12 transcriptional changes are induced by indirect effects. This is consistent with previous 13 observations and the prevailing view that CHD8 regulates the expression of many other 14 chromatin and epigenetic modifiers (13, 14). DEGs with CHD8 localisation to their promoters 15 in the Cotney data (red and purple fractions in Fig. 3G), were present in both up- and down 16 regulated gene sets, suggesting that CHD8 can function as both an activator and repressor of 17 these genes during cortical development.

18

To identify potential transcriptional co-regulators and DNA-binding factors that may cooperate with CHD8 during embryonic cortical development, Gene Set Enrichment Analysis was performed using the "ENCODE and ChEA Consensus TFs from ChIP-X" database in Enrichr (36). This analysis revealed an over-representation of E2F (E2F4, E2F6 and E2F1) targets in the upregulated genes (Suppl. Fig. 4, Suppl. Table 2). E2Fs compose a family of transcription factors with important roles in DNA replication, cell cycle progression and proliferation. CHD8 has been previously shown to be involved in E2F-dependent transcriptional activation, and is necessary for recruitment of the "activator" E2F transcription factors E2F1 and E2F3 to G1/S
 transition promoters (37). Our findings suggest that CHD8 functions as a repressor of E2F regulated genes in the developing cortex and implicate increased progenitor proliferation as a
 potential mechanism for the brain hyperplasia in these mice.

5

6 For downregulated genes, an over-representation of targets of REST (RE1-Silencing 7 Transcription factor) and the Polycomb component Suz12 was seen (Suppl. Fig. 4, Suppl. 8 Table 2). As Suz12 is essential for the activity and stability of the PRC2 complex, we asked if 9 any of the DEGs are marked by the PRC2-repressive modification H3K27me3 in normal neural 10 progenitor cells (38). The majority of DEGs that were marked by H3K27me3 in neural 11 progenitors were downregulated in hypomorphic mice (pink fractions in Fig. 3H). Thus, some 12 genes positively regulated by CHD8 are Polycomb targets in neural progenitors. Although 13 further mechanistic studies will be required to test this, these findings are consistent with CHD8 14 functioning as an antagonist of Polycomb repression as expected of a Trithorax family member. 15 REST is a master regulator of neurodevelopment, has been shown to directly interact with 16 CHD8, and is abnormally activated in *Chd8* haploinsufficient mouse brain (15). Overlapping 17 DEGs with REST ChIP-seq data (39), we found REST target genes predominantly amongst 18 downregulated genes (orange and green fractions in Fig. 3H), supporting the notion that 19 aberrant REST activation in Chd8-deficient embryonic brain may contribute to gene 20 repression. Furthermore, 40% of the downregulated REST target genes are also marked by 21 H3K27me3 in neural progenitor cells (green fractions in Fig. 3H), implying roles for both 22 REST and Polycomb in the repression of these genes in *Chd8* hypomorphs.

23

24 To provide further insights into the biological processes affected by these gene expression25 changes, gene ontology analyses were performed. These identified a significant enrichment of

cell cycle, DNA replication and repair genes in the upregulated genes in hypomorphs (Fig. 3I,
 Suppl. Table 3). Neurodevelopmental gene categories were enriched in the downregulated gene
 sets (Fig. 3I, Suppl. Table 3).

4

# 5 *Chd8* deficiency increases proliferation of cortical progenitors outside of the ventricular 6 zone.

7 To explore whether the increased expression of cell cycle and DNA replication genes in 8 hypomorphs is indeed associated with increased progenitor proliferation, we immunolabelled 9 progenitors in the G2/M phase of mitosis in coronal brain sections with an antibody against 10 phosphohistone-3B (PH3B). No difference in the number of mitotic progenitors was observed 11 in E12.5 Chd8<sup>+/-</sup> or Chd8<sup>neo/neo</sup> neocortices, compared to wildtype littermates (Suppl. Fig. 5A-12 C). To determine if differences may arise later, we performed the same experiment at E14.5 13 (Suppl. Fig. 5D,E). Again, no significant differences were seen in the numbers of proliferating 14 ventricular progenitors (Suppl. Fig. 5F). Intriguingly, a significant increase in the proliferation 15 of non-ventricular (or basal) progenitors was observed in Chd8neo/neo neocortices (Suppl. Fig. 5G). No significant differences were observed in Chd8<sup>+/-</sup>or Chd8<sup>neo/-</sup> embryos (Suppl. Fig. 16 17 5F,G), suggesting that the abnormal expansion of basal cortical progenitors only occurred 18 within a restricted window of reduced CHD8 expression.

19

To determine the identity of the non-ventricular progenitors that proliferated more in mild hypomorphs, we stained serial sections with antibodies to TBR2, a marker for intermediate progenitors, and PH3B (Fig. 4A). Counting these proliferating TBR2+ progenitors revealed a significant increase in the proliferation of these cells in *Chd8<sup>neo/neo</sup>* embryos, compared to controls (Fig. 4B). No significant changes in the number of proliferating TBR2+ progenitors was observed in other genotypes (Fig. 4B). Taken together, these experiments showed that TBR2+ intermediate progenitors accounted for the increased non-ventricular proliferation
 observed in *Chd8<sup>neo/neo</sup>* embryos.

3

4 Our data suggests that TBR2+ intermediate progenitors might be particularly sensitive to 5 reduced Chd8 expression. To find if Chd8 deficiency directly impacts gene regulation in these cells, we sorted TBR2+ and PAX6+ progenitors from E14.5 Chd8<sup>+/+</sup>, Chd8<sup>+/-</sup> and Chd8<sup>neo/neo</sup> 6 7 neocortices by FACS and compared gene expression by qRT-PCR. We selected two genes 8 identified in our RNA-seq analysis that are upregulated in Chd8neo/neo mice, Pim1, a gene 9 functionally linked to progenitor cell proliferation (40) and Axin2, a direct transcriptional target 10 and feedback antagonists of WNT-\beta-catenin signalling (41). Both Pim1 and Axin2 were 11 significantly upregulated in Chd8-deficient TBR2+, but not PAX6+ progenitors, with Axin2 12 showing a clear *Chd8* dosage-sensitive effect (Suppl. Fig 6B,C). Together, these findings show 13 that Chd8 deficiency impacts the expression of specific genes linked to neural progenitor 14 proliferation and fate specifically in TBR2+ intermediate progenitors. The gene expression changes in  $Chd8^{+/-}$  embryos may not be sufficient to increase the proliferation of these 15 16 progenitors, or may have consequences at later stages of development.

17

18 Next, we sought to identify the potential causes of cortical hypoplasia in severe hypomorphs 19 (Suppl. Fig. 2E,G). We did not detect any reduction in cortical progenitor proliferation at E14.5 20 in these mutants (Fig. 4B). Comparing gene ontology analyses between mild and severe 21 hypopmorphs (Suppl. Fig. 7 and 8; Suppl. Table 3), revealed a slight increase in the number of 22 p53-regulated genes and ribosomal genes like *Rpl26* that can augment p53 mRNA translation 23 (42) in severe hypomorphs, raising the possibility that progenitors may be more prone to 24 apoptosis in these mice. Indeed, cleaved caspase 3 (CC3) immunostaining revealed a small increase in the numbers of apoptotic cells in Chd8neo/- embryos compared to Chd8neo/neo and 25

control embryos (Fig. 4C-F), suggesting that increased cell death may be responsible for the
 brain hypoplasia in the severe hypomorphs. Thus, reducing CHD8 levels below 15% of
 wildtype, appeared to reveal another threshold below which p53-regulated genes become
 derepressed with an apparent impact on cell survival.

5

# 6 CHD8 expression is essential for repression of p53 target genes in early embryonic 7 neocortex.

As the brain phenotype and effects on p53-regulated genes and apoptosis in severe hypomorphs were subtle, we decided to explore the consequences of complete CHD8 loss (0%), by conditional deletion of *Chd8* in early neural progenitors. *Sox1-cre*-mediated deletion (Fig. 5A-B, Suppl. Fig. 9) of *loxP*-flanked (flox) exon 3 results in an early frameshift and termination of translation at amino acid 419, which is predicted to produce a protein that lacks all functional domains and results in a *Chd8*-null allele as shown previously in *Chd8*<sup>+/-</sup> mice (18).

14

15 The pan-neuronal, conditional deletion of Chd8 by Sox1-cre (Fig. 5B, Suppl. Fig. 9) resulted 16 in pronounced brain hypoplasia in homozygous conditional knockout (cKO) embryos, compared to controls (Ctrl, Chd8<sup>flox/flox</sup> (Chd8<sup>fl/f</sup>)) (Fig. 5C,D). Neocortical hypoplasia, with the 17 18 maintenance of some subcortical brain structures was evident upon histological analysis of 19 E18.5 embryos (Fig. 5C',D'). To identify the origin of these defects, cKO embryos were 20 examined at earlier stages of development. Telencephalic hypoplasia with markedly thinner 21 neuroepithelium was evident in E12.5 cKO embryos when compared to controls (Fig. 5E-F'). 22 Examination of E10.5 cKO embryos showed telencephalic vesicles of near-normal size with 23 neuroepithelia that were slightly thinner than controls (Fig. 5G-H'), suggesting that CHD8 is 24 essential for expansion of the pallium from early embryonic development.

1 To identify the potential causes of this striking phenotype, we performed RNA-seq at the onset 2 of the phenotype. RNA-seq analysis identified 2032 DEGs in E10.5 cKO telencephalic vesicles 3 compared to controls (Fig. 6A, Suppl. Table 4). KEGG pathway mapping of all dysregulated 4 DEGs identified the p53 pathway as the most significantly affected (Fig. 6B, Suppl. Fig. 10). 5 Interestingly, GO analysis identified cell cycle as the most dysregulated bioprocess (Suppl. 6 Table 4), with a slight majority of genes within this category downregulated (60 out of 111). 7 Quantitative RT-PCR (qRT-PCR) confirmed significant upregulation of multiple p53-8 regulated genes (Fig. 6C). Furthermore, genes normally upstream of p53, Atr and Atm, and 9 Trp53 (the gene encoding p53 itself) were not affected by Chd8 deletion (Fig. 6C), consistent 10 with a role for CHD8 in directly repressing p53 target genes (10).

11

12 To ask if increased p53 pathway activity was responsible for the cKO phenotype, we reduced 13 p53 gene expression in the neuronal lineage to test if this can reduce the severity or incidence 14 of phenotypic abnormalities. Neocortical hypoplasia was partially rescued in Sox1-Cre;Chd8<sup>f/f</sup>;Trp53<sup>f/+</sup> (conditional knockout p53 heterozygous, cKO-p53het) embryos (Fig. 15 16 6D), providing strong genetic evidence that this phenotype was caused by elevated p53 17 signaling. A substantial increase in apoptosis was observed in the cKO embryos (Fig. 18 6E,F,H,I). The number of apoptotic cells was significantly reduced in the pallium of cKO-19 p53het embryos, compared to cKO embryos (Fig. 6F-I). We also noted the presence of certain 20 cell cycle inhibitors amongst genes upregulated in the cKO (e.g. p21/CDKN1A)(Fig. 6C). 21 Therefore, we investigated neural progenitor proliferation. Quantification of PH3B+ cells in 22 the ventricular zone of the neocortex confirmed a strong reduction in cell proliferation in cKO 23 embryos (Fig. 6J,J',K,K',M). Cell proliferation was slightly increased in cKO-p53het embryos 24 compared to cKO embryos (Fig. 6L,L',M), consistent with only a partial rescue of neocortical size in these animals (Fig. 6D). The visualisation of proliferating BrdU+ cells in the same
 sections appear to support this conclusion (Fig. J-L').

3

4 To determine if neuronal differentiation was affected in these mutants, we immunostained for 5 Doublecortin (DCX). DCX+ cells were present in the preplate (pp) at the pial surface in all 6 control embryos (n=3/3; Fig. 6N,N'). Ectopic clusters of DCX+ cells were visible throughout 7 the neural tube of all cKO embryos (n=4/4), including the ventricular zone (Fig. 6O,O'), 8 suggesting a precocious and disorganised differentiation of progenitors compared to controls 9 (p=0.029, Fisher's exact test). DCX+ cell positioning was normalised in all cKO-p53het embryos (n=4/4; Fig. 6P,P') indicating a significant rescue of this phenotype compared to cKO 10 11 embryos (p=0.029, Fisher's exact test).

12

Taken together, these data identify CHD8 as an essential repressor of p53 pathway activation during neocortical development. CHD8 loss leads to increased apoptosis, reduced neural progenitor proliferation and precocious cell differentiation during early embryonic development, resulting in severe neocortical hypoplasia by the end of gestation.

#### 1 Discussion

2 Human genetic studies have identified heterozygous, likely gene disrupting mutations in CHD8 3 as a possible cause of ASD and macrocephaly. Chd8 heterozygous mice have been generated 4 by several groups, but these mice were found to exhibit relatively subtle brain overgrowth (15-17, 19). Observations of relatively small transcriptional changes in the mid-gestation  $Chd8^{+/-}$ 5 6 mouse brain appeared at odds with the many genes dysregulated upon Chd8 knockdown in 7 progenitor cell lines and after in utero electroporation (13, 14, 20). Together, these studies led 8 us to explore whether different sensitivities to reduced CHD8 dosage might account for some 9 of these inconsistencies. A comparison of brain size, gene expression and neural progenitor 10 fate in a mouse Chd8 allelic series yielded several key findings: 1) A small additional reduction in Chd8 expression in mild hypomorphs compromised the capacity of neural progenitor cells 11 12 to maintain stable expression of over 2000 genes in the mid-embryonic neocortex, which 13 included over 140 ASD-associated genes; 2) CHD8 has a key role in limiting the expansion of 14 TBR2+ intermediate progenitors, a population particularly important for human cortical 15 development; 3) A gradual reduction in CHD8 expression can have non-linear effects on gene 16 expression and brain growth (Fig. 7). In addition to the precipitous gene expression changes in mild hypomorphs, we observed brain hyperplasia in  $Chd8^{+/-}$  and  $Chd8^{neo/neo}$  mice, but brain 17 18 hypoplasia in severe hypomorphs and conditional knockouts (Fig. 7). Together, these findings 19 indicate that CHD8 levels need to be tightly regulated during development and that the 20 interpretation of experimental manipulations that involve Chd8 knock-down should consider 21 these non-linear, threshold effects.

22

#### 23 CHD8 as a phenotypic capacitor

It has been posited previously that ASD-associated chromatin remodelling factors may act as phenotypic capacitors, buffering against perturbations to normal development in order to

1 maintain stable phenotypes (43). Heterozygosity for a capacitor is predicted to result in a loss 2 of robustness, such that the cells are more susceptible to additional genetic and non-genetic 3 risk factors. Our findings that over 2200 genes, many of which are ASD risk factors, became 4 dysregulated by a small additional decrease in CHD8 dosage below 50%, supports the idea that 5 some neurodevelopmental genes and processes may be close to a critical threshold in the Chd8 6 heterozygous neocortex and therefore easily perturbed by small additional changes. It will be 7 important to determine if specific ASD-associated CHD8 mutations in humans reduce CHD8 8 function by more than 50% by dominant negative mechanisms, as our findings would predict 9 these mutations to be significantly more pathogenic than purely haploinsufficient mutations. It 10 is also important to consider that the C57BL/6 genetic background has been used for all Chd8 11 heterozygous mouse studies so far. This background may be protective and more robust in the 12 context of *Chd8* haploinsufficiency, such that different, or more severe phenotypes may emerge 13 on different genetic backgrounds. We report a significant effect of sub-haploinsufficient levels 14 of Chd8 expression on the proliferation of intermediate progenitors in the E14.5 embryonic 15 cortex. It will be of interest to determine if other cell types relevant to CHD8 function in the 16 brain, like oligodendrocytes (44), exhibit similar Chd8 gene dosage sensitive responses.

17

#### 18 **CHD8** regulates the proliferation of non-ventricular cortical progenitors

Our findings raise the possibility that brain development in human and mouse differ in sensitivity to a similar reduction in CHD8 function, such that *CHD8* heterozygosity may cause more pronounced changes to brain growth and transcriptional regulation in the developing human brain. In this regard, fundamental differences in mouse and human brain development may result in *CHD8* haploinsufficiency having more pronounced effects on human brain development. Comparative studies of gyrencephalic and lissencephalic animals have identified important differences in the capacity of non-ventricular progenitors to expand and

1 subsequently contribute to cortical expansion. This population of progenitors consists of outer 2 radial glia cells (oRGs), and TBR2-expressing intermediate progenitor cells (IPs) (45). In 3 humans, oRGs are located in an expanded outer-subventricular zone (oSVZ) and are capable 4 of asymmetric divisions that generate an oRG daughter cell, which maintains the pool of non-5 ventricular progenitors, and an IP daughter cell that can undergo transit-amplifying divisions 6 to expand and generate neuronal progeny (46). By contrast, mouse oRGs primarily undergo 7 self-renewing, neurogenic divisions and populate a non-ventricular region lacking the distinct, 8 expanded cytoarchitecture of the oSVZ typically seen in gyrencephalic species (47). 9 Furthermore, mouse IPs likely possess a more limited capacity for self-renewal, as a majority 10 of mouse IP divisions appear to generate two neuronal daughter cells (48, 49). Therefore, if 11 CHD8 has an especially crucial role in regulating the expansion of TBR2+ progenitors also in 12 the human brain, then it is possible that CHD8 deficiency in these cells could result in more 13 pronounced phenotypes with regard to cortical over-growth and circuit disruption in humans. 14 The lack of exacerbated ASD-linked behavioural phenotypes in *Chd8<sup>neo/neo</sup>* mice is consistent 15 with this notion.

16

17 Interestingly, we also note that Bernier et al. previously identified an enrichment for CHD8 18 expression in areas outside the ventricular zone in human mid-fetal cortex (6), further 19 supporting the idea that CHD8 may have an important role in regulating expansion of these 20 cells. An analysis of neural progenitor subsets in *CHD8*-deficient human brain organoids 21 should be a viable way to test this hypothesis.

22

#### 23 CHD8 is an essential repressor of p53 in neural progenitors

One of the most striking non-monotonic effects of *Chd8* efficiency reported here is brain
hypoplasia in pan-neuronal *Chd8* cKO mice, partly as a result of de-repression of the p53

1 pathway in early neuroepithelial cells. This discovery identifies CHD8 as a critical repressor 2 of p53 target gene activation in neural progenitors. Our findings suggest that very low levels 3 of CHD8 are sufficient to repress p53 target genes and maintain neural progenitor self-renewal. 4 One could speculate that the CHD8-dependent recruitment of histone H1 to p53 target genes 5 to initiate a cooperative process of chromatin compaction (10), may require lower levels of 6 CHD8 than another process that is dependent upon the constitutive recruitment of RNA 7 polymerase (50) or other co-activating factors by CHD8 (Fig. 7). Our gene expression and 8 apoptosis data suggest that CHD8 protein levels in *Chd8<sup>neo/-</sup>* embryos were close to this critical 9 threshold. Interestingly, Cotney et al. also reported p53 signaling as one the most dysregulated 10 pathways upon CHD8 knock-down in human neural stem cells (13). However, other studies in 11 human cell lines have not demonstrated the same changes, including an in vitro knock-down 12 of CHD8 to 20-25% of control levels in human SK-N-SH neural progenitor cells (51). 13 Intriguingly, CHD8, and its family member CHD7, also maintains the survival of 14 oligodendrocyte precursors by inhibiting the p53 pathway, although this appears to be 15 primarily mediated via direct repression of the p53 gene (52). Together, these findings suggest 16 that transcriptional responses to reduced CHD8 levels are highly context-dependent and may 17 help shed light on reports that Chd8 knock-down in utero led to reduced proliferation and 18 enhanced differentiation of neural progenitor (20).

19

#### 20 Behavioural phenotypes in *Chd8*-deficient mice.

A number of *Chd8*<sup>+/-</sup> mouse models have been reported. Given the strong association between
CHD8 mutations and ASD in humans, one might have expected these mice to exhibit robust,
ASD-like behaviours. However, that is not the case, a finding not that surprising if one takes
into account the pronounced differences in brain size and behaviour between these species.
Nevertheless, we tested whether mice with more pronounced brain and gene expression

phenotypes exhibit more pronounced behavioural phenotypes. With the possible exception of
 anxiety, the behavioural phenotypes of *Chd8*<sup>+/-</sup> and hypomorphic mice were remarkably
 similar, including robust, reproducible hypo-activity (18).

4

#### 5 Limitations

6 As with all other Chd8 mouse studies so far, our models were on a C57BL/6 genetic 7 background. Different, or more severe phenotypes may emerge on different genetic 8 backgrounds. Given the significant postnatal lethality of Chd8 hypomorphic mice, we cannot 9 exclude the possibility that the reason for not observing a particularly prominent exacerbation 10 of behavioural phenotypes compared to heterozygous mice, may be that only mildly affected, surviving mice could be behaviourally phenotyped. Furthermore, unlike Chd8<sup>+/-</sup> mice, all 11  $Chd8^{neo/neo}$  mice were born to  $Chd8^{neo/+}$  mothers, and the posibility that differences in maternal 12 13 care could account for subtle behavioural differences cannot be ruled out. Recent work have 14 reported sexually dimorphic effects in another *Chd8* model (19). We did not observe significant 15 behavioural differences between males and females in our studies, and the structural, 16 molecular and developmental experiments reported here were performed with mixed sex 17 samples. We therefore cannot rule out sex-specific effects in gene expression and perhaps even 18 developmental phenotypes. Our findings identify an important role for the autism-associated 19 factor CHD8 in controlling the proliferation of intermediate progenitors in the mouse 20 neocortex. Our analysis of TBR2+ intermediate progenitors show a robust increase in the proliferation of these cells in *Chd8* hypomorphs, but not *Chd8*<sup>+/-</sup> mice (Fig. 4), despite the latter 21 22 showing significant alterations in gene expression (Suppl. Fig. 6). We cannot at this stage rule 23 out the possibility that the dynamics of neural progenitor proliferation and differentiation differ 24 in heterozygous and hypomorphic mice, and that intermediate progenitors over-proliferate also in Chd8<sup>+/-</sup> mice, but at a different developmental stage. A comprehensive, timed analysis of 25

1 TBR2+ progenitor fate will be required to test this possibility. We propose that CHD8 also 2 regulates intermediate progenitor proliferation in human brain development, as indeed 3 suggested by CHD8 expression studies (6), but studies on human cells are required to confirm 4 this. Finally, we show that CHD8 represses p53-regulated genes and that p53 pathway 5 hyperactivation in neuroepithelial cells that lack CHD8 is at least in part responsible for cellular 6 phenotypes that can lead to cortical hypoplasia. These findings do not exclude the contribution 7 of other pathways and cellular mechanisms to the hypoplasia phenotype.

8

#### 9 Conclusion

In conclusion, our analysis of an allelic series of *Chd8*-deficient mice has identified clear nonmonotonic effects on gene expression and brain growth (Fig. 7). Recognition of the differing sensitivities of important cellular processes to CHD8 dosage and how small differences in CHD8 levels may lead to disproportionally large differences in phenotype is an important step in understanding the context-specific transcriptional roles of CHD8 in brain development.

#### 1 Figures

2

#### 3 Fig 1. Brain hyperplasia in *Chd8* heterozygous and mild hypomorphic mice.

4 A) Diagrammatic representation of the *Chd8* allele containing the neo cassette between exons

- 5 3 and 4. Exon 3 splicing to exon 4 yields a 150bp product (\*) by RT-PCR using primers F and
- 6 R. Aberrant splicing from exon 3 into the neo cassette yields a 246bp product (\*\*) with primers
- 7 F and neo.

1 B) Quantitative RT-PCR of *Chd8* transcripts in E9.5-E10.5 neocortices of indicated genotypes.

2 C) Estimation of CHD8 protein levels in E12.5 neocortices by Western blot.

3 D) High-resolution 7T structural MRI coronal images of  $Chd8^{+/-}$  (n=12, all males, 22 weeks

4 old) and  $Chd8^{neo/neo}$  brains (n= 13, 8 males, 5 females, 16 weeks old), from posterior (top) to

5 anterior (bottom) are shown. Absolute volumetric differences, relative to wildtype controls

- 6 (n=30, 26 males, 4 females) are coloured according to the scale on the right. Some regions with
- enlarged volumes are labeled as follows: NCtx neocortex, EcC ectorhinal cortex, EnC –
   entorhinal cortex, HC hippocampus, Cb cerebellum.
- 9 E) Absolute volumes relative to wildtypes are plotted for whole brain, neocortex and several
- 10 other brain regions for the different genotypes as indicated. -FDR<0.15, \*FDR<0.05,
- \*\*FDR<0.01. See also Supplementary Table 1. MRI data from  $Chd8^{+/-}$  and littermate control
- 12 mice used for comparison are from Suetterlin et al. (18).

#### 4 Fig 2. Behavioural assessment of mild *Chd8* hypomorphic mice.

5 A-J) Behavioural assessments of a cohort of adult  $Chd8^{neo/neo}$  (neo/neo, n= 24; 14 males, 10 6 females, A-B, D-E, G-I or n=15; 10 males, 5 females, F,K or n=11; 6 males, 5 females, J) and 7 *Chd8*<sup>+/+</sup> (+/+, n=41; 26 males, 15 females, A-B, D-E, G-I or n=31, 21 males, 10 females, F,K or n=12; 6 males, 6 females, J) and pup Chd8neo/neo (neo/neo, n=10; 4 males, 6 females, C) and 8 9  $Chd8^{+/+}$  (+/+, n=12; 6 males, 6 females, C) mice.  $Chd8^{+/+}$  animals are illustrated using filled circles, dotted lines with grey bars and Chd8neo/neo animals with open triangles, solid lines and 10 11 open bars. Apart from USVs (C), all other tests were conducted on young adults 6-14 weeks 12 of age.

13

A) Duration, in seconds, spent in each chamber of the three-chamber sociability test. All mice spent a significantly higher proportion of time in the chamber with the age- and sex- matched stranger con-specific mouse compared to the other chambers. Mean±SEM; \*\*\*<0.001

17 (between-subjects ANOVA with student's t-test as post-hoc analysis).

B) Duration, in seconds, of social investigation over a three-minute period. Social investigation
 was defined as the combined total duration of head, body and anogenital sniffing of a
 conspecific mouse. Mean±SEM (between-subjects ANOVA).

21 C) The mean number of ultrasonic vocalisations per minute on indicated postnatal days.

22 Mean±SEM (repeated-measures ANOVA).

- 23 D) Graph demonstrating the performance in the olfactory habituation/dishabituation test.
- 24 Mean±SEM (repeated-measures ANOVA).

- 1 E) The duration, in seconds, mice spent self-grooming during the 10-minute self-grooming test.
- 2 Mean±SEM (between-subjects ANOVA).
- 3 F) The average number of marbles buried, out of a maximum of 12, within a 30-minute period
- 4 period. Mean±SEM; \*<0.05, \*\*<0.01 (repeated-measures ANOVA with student's t-test as
- 5 post-hoc analysis).
- 6 G)Representative ethovision tracks of a  $Chd8^{neo/neo}$  (neo/neo) and  $Chd8^{+/+}$  (+/+) animal
- 7 plotting their movements during the 10-minute open field task.
- 8 H) The percentage of time spent in the centre of the open field arena during the 10-minute test.
- 9 Mean±SEM; \*\*p<0.01 (between-subjects ANOVA).
- 10 I) The total distance travelled in the outer part of the open field arena over a 10-minute time-
- 11 period. Mean±SEM; \*\*\*<0.001 (between-subjects ANOVA).
- 12 J) The total activity counts per 12h period on running wheels in the homecage during 7 days
- 13 of dark-phase recording. Mean±SEM; \*p<0.05 (repeated-measures ANOVA).
- 14 K) The mean latency of mice to fall from the rotarod. Mean±SEM (repeated-measures 15 ANOVA).
- 16

2 Fig 3. Gene expression changes in *Chd8*-deficient neocortices.

- 3 A) Volcano plot indicating all DEGs detected by DESeq2 in E12.5 *Chd8*<sup>+/-</sup> embryonic
- 4 cortices. Each point represents an individual gene, and all heterozygote DEGs (FDR <0.05)
- 5 are highlighted in red. n = 3 per condition.

- 1 B) Volcano plot showing all DESeq2 detected DEGs in E12.5 neo/neo cortex. All
- 2 differentially expressed genes (FDR < 0.05) are highlighted in red. n = 3 per condition.
- 3 C) Volcano plot of all DESeq2 detected DEGs in E12.5 neo/- cortex. All differentially
- 4 expressed genes (FDR < 0.05) are highlighted in red. n = 3 per condition.
- 5 D) Heatmap of genes differentially expressed in neo/neo and neo/- embryos, indicating
- 6 transformed relative expression levels in +/+, +/-, neo/neo and neo/- embryos.
- 7 E) Mean normalised count of aligned RNA-seq reads for a selection of genes that were
- 8 differentially expressed in the mild and severe hypomorphs.
- 9 F) Venn diagram showing extent of overlap between neo/neo and neo/- DEGs and ASD
- 10 associated genes obtained from the SFARI Human Gene database
- 11 (<u>https://gene.sfari.org/autdb/HG\_Home.do</u>, accessed March 2018).
- 12 G) Breakdown of neo/neo and neo/- DEGs that are ASD associated, DEGs with known CHD8
- 13 binding sites in E17.5 mouse neocortex, human mid foetal cortex and NSCs; and DEGs that
- 14 are both ASD associated and have known CHD8 binding sites. Downregulated genes are
- 15 denoted by a negative number.
- 16 H) Breakdown of neo/neo and neo/- DEGs with H3K27me3 in neural progenitors, DEGs with
- 17 known REST binding sites, and DEGs that have been shown to have both H3K27me3 in neural
- 18 progenitors and REST binding sites. Downregulated genes are denoted by a negative number.
- 19 I) Gene Ontology (GO) analysis of up and down-regulated neo/neo and neo/- DEGs under the
- 20 "Biological Processes" category. The five most significant hits are shown for each set. See also
- 21 Supplementary Table 3.
- 22

- 1
- 2

#### 3 Fig 4. Increased proliferation of basal neural progenitors in *Chd8<sup>neo/neo</sup>* embryos.

4 A) Immunohistochemistry to detect PH3B+ (blue) and TBR2+ (green) nuclei in coronal 5 sections through the telencephalon of E14.5 embryos. White arrowheads indicate 6 PH3B+/TBR2+ nuclei.White box is shown as zoomed inset containing a double positive cell.

B) Quantification of TBR2+/PH3B+ cells per 100 $\mu$ m of neocortex in E14.5 embryos (+/+,

8 n=20; neo/+, n=9; +/-, n=7; neo/neo, n=6; neo/-, n=8;  $Mean\pm SEM$ , \*p<0.05, \*\*\*p<0.001, 0 ANOVA followed by Tykey's multiple comparisons test)

9 ANOVA followed by Tukey's multiple comparisons test).

10 C-E) Cleaved caspase 3 (CC3) immunostaining of dorsal neocortex of E14.5 embryos. Black 11 arrows indicate CC3+ cells and black box in E highlights area shown in zoomed inset 12 containing a CC3+ cell. Scale bar =  $100\mu m$ .

F) Relative quantification of CC3+ cells in neocortex of E14.5 *Chd8* mutant embryos,
 normalised to respective wildtype littermates (+/+, n=17; neo/+, n=7; neo/neo, n=6; neo/-,

- 15 n=11; Mean±SEM \*\*p<0.01). Embryos used in these experiments were from 8 different litters.
- 16
- 17

### Fig 5. Conditional deletion of *Chd8* from the embryonic neuroepithelium results in severe hypoplasia of the telencephalon and neocortex

A) Schematic representation of the wildtype (wt) mouse *Chd8* gene (*Chd8<sup>wt</sup>*), targeting construct for homologous recombination in embryonic stem cells, the *Chd8* targeted allele (*Chd8<sup>neo</sup>*), the *Chd8* conditional allele after Flp-mediated excision of the neomycin resistance cassette (*Chd8<sup>flox</sup>*) and the *Chd8<sup>null</sup>* allele produced by Cre-mediated deletion of exon 3. Boxes represent exons, with exon 1 (Ex1) to 6 and 13 shown and exon 3 filled in black. The blue box represents a neomycin resistance cassette (neo), red triangles represent *loxP* sites and tan

11 triangles *frt* sites. The long 9.45 kb (5') homology arm is indicated in red and the short 4.4 kb

12 (3') homology arm in green in the targeting construct.

13 B) X-gal staining of a Sox1-Cre;R26R embryo at E9.5 (left); and immunostaining for CHD8

- 14 protein on Chd8<sup>flox/flox</sup> (Ctrl) and conditional knockout Sox1-Cre;Chd8<sup>flox/flox</sup> (cKO) E10.5
- 15 neural tube (right). Scale bar =  $50\mu m$
- 16 C,D) Wholemount images of E18.5 brains of a representative Ctrl and cKO embryo, anterior
- 17 is to the right. Scale bar = 1mm
- 18 E,F) Wholemount images of embryonic day 12.5 heads, anterior to the right. Scale bar = 1mm
- 19 G,H) Wholemount images of E10.5 embryos, anterior to the right.
- 20 C' –H') Cresyl violet-stained frontal sections through brains as indicated in C-H above. Scale
- 21 bars = 500µm (C'-D') and 200µm (E'-H'). The following subcortical structures are labelled in
- 22 Ctrl (C') and cKO (D') at E18.5: NCtx: Neocortex, mhN: medial habenular nucleus, vmt:
- 23 ventral medial thalamic nucleus, amN: amygdaloid nucleus. Images are representative of at
- 24 least 3 independent samples.

#### 2 Fig 6. Repression of p53 target genes by CHD8 is necessary for normal brain growth.

- A) Volcano plot of RNA-seq data illustrating in red genes that are differentially expressed (FDR<0.05) in E10.5 cKO telencephalon, with p53 pathway genes labelled.
- 5 B) Pathway enrichment analysis of differentially expressed genes, with the top KEGG pathway
- 6 terms shown. See also Supplementary Table 4.
- 7 C) qRT-PCR validation of a selection of p53 pathway genes identified by RNA-seq (n=4 for
- 8 each condition. Mean±SEM; \*p<0.05, \*\*\*p<0.001, student's t-test).
- 9 D) Wholemount brains from E18.5 Ctrl, cKO and cKO-p53het mice are shown, anterior to the
- 10 top. Data are representative of 6 embryos per genotype. Scale bar = 1mm

- 1 E-G) Cleaved caspase 3 (CC3) immunohistochemistry (brown) on frontal sections through the
- 2 telencephalon of E12.5 embryos. Scale bar =  $200 \mu m$ .
- 3 H) Quantification of CC3+ cells/ $\mu$ m<sup>2</sup> of the pallium in embryos of each genotype (Ctrl, n=4;
- 4 cKO, n=3; cKO-p53het, n=3; Mean±SEM; \*p<0.05, \*\*p<0.01, ANOVA followed by Tukey's
- 5 multiple comparisons test).
- 6 I) Quantification of CC3+ cells/µm<sup>2</sup> of the subpallium (medial ganglionic eminence) in
- 7 embryos of each genotype (Ctrl, n=4; cKO, n=3; cKO-p53het, n=3; Mean±SEM; \*p<0.05,
- 8 \*\*p<0.01, ANOVA followed by Tukey's multiple comparisons test).
- 9 J-L) Immunohistochemistry to detect BrdU+ (red) and phospho-histone 3B (PH3B)+ nuclei in
- 10 frontal sections through the telencephalon of E12.5 embryos. Scale bar =  $100 \mu m$ .
- 11 J'-L') Magnified images of the boxed neocortical regions in J-L, with the ventricular zone (vz)
- 12 at the bottom and pial surface at the top. Scale  $bar = 25 \mu m$
- 13 M) Quantification of PH3B+ cells/ $\mu$ m of neocortical ventricular surface (Ctrl, n=4; cKO, n=3;
- 14 cKO-p53het, n=3; Mean±SEM; \*p<0.05, \*\*p<0.01, ANOVA followed by Tukey's multiple
- 15 comparisons test).
- 16 N-P) Immunostaining of frontal E12.5 sections for DCX (green) to label differentiating
- 17 neurons, with nuclei counterstained with Hoechst 33342. Scale bar =  $200\mu m$ .
- 18 N'-P') Magnified images of N-P, with the ventricular zone (vz) at the bottom and pial surface
- 19 (pp) at the top. Scale bar =  $25\mu m$ .
- 20 21

## Fig 7. The non-monotonic relationship between CHD8 protein levels, gene expression and brain size.

5 The effects of gradual reductions in CHD8 protein levels to ~50% (heterozygous), ~35%

6 (mild hypomorph), ~10% (severe hypomorph) and 0% (conditional knockout) on the

- 7 transcription of neurodevelopmental, cell cycle and p53-regulated genes and brain size are
- 8 depicted. CHD8 appears to function primarily as a positive regulator of neurodevelopmental
- 9 genes via recruitment to H3K4me3-modified (yellow ball) histones (gray spool), presumably
- 10 via enabling the recruitment of key transcription factors (TF). A sharp reduction in the 11 expression of many of these genes (arrow) is only observed in E12.5 neocortex when CHD8
- 12 levels are reduced to below a threshold less than haploinsufficient levels. CHD8 appears to
- repress E2F-regulated cell cycle genes in this context, with significant induction only
- becoming evident at sub-haploinsufficient levels, although low expression increases (grey
- 15 arrow) likely drives subtle increases in proliferation in the heterozygous state. Cell cycle
- 16 genes are dysregulated in the opposite direction in the cKO, suggestive of non-monotonic
- 17 effects (blue arrow). CHD8 can interact with p53 and histone 1 (H1), leading to stable
- 18 heterochromatin formation and repression of p53 target genes. A few p53-regulated genes
- 19 become activated in hypomorphic mice (grey arrow), but the majority remains fully repressed
- 20 with de-repression only becoming evident upon complete CHD8 loss. Note the different
- 21 CHD8 thresholds for different groups of genes (broken lines) and the non-monotonic effects
- 22 on gene expression and over-all brain size.
- 23

#### 3 Supplementary Fig 1. CHD8 expression is reduced in Chd8<sup>+/-</sup>, Chd8<sup>neo/neo</sup> and Chd8<sup>neo/-</sup>

#### 4 embryo telencephalic vesicles at E12.5

- 5 Whole cell lysate from telencephalic vesicles of indicated genotypes were subjected to
- 6 western blot analysis using an anti-CHD8 antibody targeting the N-terminal portion of the
- 7 protein, utilising either GAPDH (A) or  $\beta$ -actin as a loading control (B-D). Arrows indicate
- 8 bands corresponding to target protein. The band just below is a non-specific band. Labels
- 9 above individual wells indicate biological replicates used.

## Supplementary Fig 2. Brain hypoplasia and unilateral anopthalmia in severe *Chd8* hypomorphic mice

- 4 A-D) Representative wholemount images of brains from E18.5 severe *Chd8* hypomorph
- 5 (neo/-) and Chd8 heterozygous (+/-) embryos, with corresponding wildtype (+/+) littermate
- 6 controls (A for B and C for D).
- 7 E) Overlay of an E18.5 *Chd8<sup>neo/-</sup>* brain on to a littermate control brain. Note the smaller brain of
- 8 the hypomorph.
- 9 F) Overlay of an E18.5  $Chd8^{+/-}$  brain on to a littermate control brain.
- 10 G) Absolute brain weights of wildtype control (+/+),  $Chd8^{+/-}$  (+/-), and  $Chd8^{neo/-}$  (neo/-) brains.
- 11 Note the significantly smaller brain weights in  $Chd8^{neo/-}$  mice compared to controls, and the
- 12 trend towards heavier brains in  $Chd8^{+/-}$  embryos. n = 17 (+/+), n= 10 (+/-), n=8 (neo/-). Values
- 13 plotted are mean  $\pm$  SD. Scale bar = 2mm.
- 14 H) Lateral view of heads of E18.5 *Chd8<sup>neo/-</sup>* embryos with unilateral anopthalmia. White
- 15 arrowheads indicate the presence of one eye on the left side of the head, whereas on the right
- 16 side no apparent eye developed in the presumptive eye socket region. This was observed in
- 17 two out of four  $Chd8^{neo/-}$  embryos examined for this phenotype, each from a different
- 18 pregnancy.

# Supplementary Fig 3. qRT-PCR validation of differential gene expression in E12.5 neocortex.

4 A-E) Relative expression levels for a selection of DEGs detected in the E12.5 RNA-seq as

5 determined by qRT-PCR. cDNA for qRT-PCRs was reverse transcribed from total RNA

- 6 extracted from E12.5 neocortex for the genotypes shown. Relative expression levels were
- 7 calculated using the  $2^{-\Delta\Delta CT}$  method and *Canx*, *Sdha* and/or *Ywhaz* were used as endogenous
- 8 control genes. (n = 3 per condition, Mean $\pm$ SD, \*p<0.05, \*\*p<0.01, student's t-test).

#### **ENCODE and ChEA Consensus TFs from ChIP-X**

1

#### 2 Supplementary Fig. 4. Analysis of transcription factor enrichment using Enrichr

3 Putative regulatory transcription factors were determined with Enrichr using the "ENCODE

4 and ChEA Consensus TFs from ChIP-X" database with all upregulated DEGs (top red

5 panels) and downregulated DEGs (bottom blue panels) detected below a 0.05 FDR. The top 5

6 most significant hits are shown.

### 2 Supplementary Figure 5. Non-ventricular progenitor proliferation is increased at E14.5

#### 3 in *Chd8<sup>neo/neo</sup>* embryos.

- 4 A,B) Immunostaining to detect PH3B+ nuclei (brown) in coronal sections through the telencephalon of E12.5 embryos of indicated genotypes. Scale bar =  $100\mu m$ .
- 6 C) Quantification of PH3B+ cells per 100μm of ventricular zone in E12.5 embryos (+/+, n=5;
- 7 +/-, n=5; +/+, n=5; neo/neo, n=4; Mean $\pm$ SEM, student's t-test).
- 8 D,E,F,G) Immunostaining to detect PH3B+ nuclei (brown) in coronal sections through the
- 9 telencephalon of E14.5 embryos of indicated genotypes. Inset shows high magnification view
- 10 of boxed area. Scale bar =  $100\mu m$ .
- 11 F,G) Quantification of PH3B+ cells per 100µm in ventricular (F) or non-ventricular (G) areas
- 12 of neocortex in E14.5 embryos (+/+, n=6; +/-, n=6; +/+, n=5; neo/neo, n=3; +/+, n=3; neo/-,
- 13 n=4; Mean±SEM, \*\*p<0.01, ANOVA followed by Tukey's multiple comparisons test).
- 14 Mutant and control samples for these experiment were obtained from 2-3 separate litters.
- 15

Supplementary Figure 6. Gene expression in TBR2+ and PAX6+ neuronal progenitors
 in *Chd8* mutant embryos.

5 A) Schematic of FACS/RT-PCR workflow. The neocortex was dissected from E14.5

6 embryonic brain and dissociated into single cell suspension. Cells were stained for TBR2

7 (AlexaFluor 488) and PAX6 (PE) and TBR2+ and PAX6+ populations isolated by FACS.

8 RNA was extracted from samples, reverse transcribed to cDNA and quantitative PCR was

9 performed. qRT-PCR analysis confirms enriched expression of *Tbr2* in Tbr2+ cells and

- 10 enriched expression of *Pax6* in Pax6+ cells, although the latter is not statistically significant,
- 11 probably due to low Pax6 expression in early TBR2+ progenitors. B,C) Fold expression
- 12 changes in *Pim1* (B) and *Axin2* (C) in *Chd8*<sup>+/-</sup> and *Chd8*<sup>neo/neo</sup> cells compared to WT cells are
- 13 shown (n=3 for each condition). Mean±SEM, \*p<0.05, \*\*p<0.01, unpaired student's t-test.
- 14

1

## Supplementary Figure 7. Functional Enrichment Analysis of differentially expressed genes (DEGs) in neo/neo embryos.

- 5 DEGs (FDR <0.05) were subjected to KEGG pathway enrichment analysis (Top Panels), and
- 6 screened for Gene Ontology terms in Molecular Function (Middle Panels) and Biological
- 7 Process (Bottom Panels) categories using the DAVID knowledgebase. In each category, the
- 8 25 most significant terms are shown and the p53 pathway indicated in purple.
- 9
- 10

1

## Supplementary Fig 8. Functional Enrichment Analysis of differentially expressed genes (DEGs) in neo/- embryos.

- 5 DEGs (FDR <0.05) were subjected to KEGG pathway enrichment analysis (Top Panels),
- 6 screened for Gene Ontology terms in Molecular Function (Middle Panels) and Biological
- 7 Process (Bottom Panels) categories using the DAVID knowledgebase. In each category, the
- 8 25 most significant terms are shown and the p53 pathway indicated in purple.
- 9

- 1
- 2

Supplementary Fig 9. CHD8 is highly expressed during mid-embryonic stages and
efficiently removed by recombination with *Sox1-Cre*.

5 A-C'') Immunostaining of E12.5, E11.5 and E10.5 brain sections with an anti-CHD8 antibody.

6 Higher magnification images of dorsal cortex (boxed areas) are shown in A'-C". Note the

7 presence of nuclear CHD8 protein throughout the pallium and subpallium at E12.5 - E10.5 and

8 higher levels of CHD8 immuno-staining in dorsal (A'-C') compared to ventral pallium (A''-

- 9 C'').
- 10 D-F') Conditional pan-neuronal deletion of *Chd8* results in widespread loss of CHD8 protein 11 in all brain structures. Higher magnification images of dorsal cortex (boxed areas) are shown
- 12 in D'-F'. Note the loss of CHD8 immunostaining in the neural tube, with unchanged expression
- 13 in other tissues. The data is representative of 3 control and 3 cKO embryos of each stage. Scale
- 14 bars: A-F: 500µm, A'-F', A''-C'': 50µm
- 15

#### Supplementary Fig 10. Diagram of the p53 pathway, with differentially expressed genes in the cKO highlighted. KEGG pathway mapping using DAVID of all differentially expressed genes revealed

- perturbed expression of 27 components of the p53 signalling pathway. Upregulated genes are
- boxed in red, downregulated genes in purple, and unchanged genes in blue. Solid lines
- indicate direct interactions whereas broken lines show indirect effects. Chd8 depletion
- resulted in more upregulated (22 genes) than downregulated (5 genes) p53 pathway
- components. The expression of p53 itself (green) was not significantly changed. This figure
- is adapted from KEGG map mmu04115 (53).
- Supplementary Table 1: Raw MRI volumetric data, accompanies Fig. 1D,E.
- Supplementary Table 2: RNA-seq data from E12.5 neocortices, accompanies Fig. 3.
- Supplementary Table 3: Gene ontology and pathway analyses of E12.5 RNA-seq data, accompanies Fig. 3I.
- Supplementary Table 4: RNA-seq and gene ontology analysis of E10.5 cKO telencephalic vesicles, accompanies Fig. 6A,B.
