1 **Abstract**

2 The human gut microbiome plays a key role in human health¹, but 16S characterization lacks quantitative
3 functional annotation². The fecal metabolome provides a functional readout of microbial activity and could
4 be used as an intermediate phenotype mediating these interactions³. In the first comprehensive description
5 of the fecal metabolome, examining 1116 metabolites of 786 individuals from a population-based twin
6 study (TwinsUK), the fecal metabolome was found to be only modestly influenced by host genetics
7 ($h^2=17.9\%$). One replicated locus at the *NAT2* gene was associated with fecal metabolic traits. The fecal
8 metabolome largely reflects gut microbial composition explaining on average 67.7% ($\pm 18.8\%$) of its variance.
9 It is strongly associated with visceral fat mass, illustrating potential mechanisms underlying the well-
10 established microbial influence on abdominal obesity. Fecal metabolic profiling appears as a novel tool to
11 explore links between microbiome composition, host phenotypes, and heritable complex traits.

12

1 There is growing evidence that the gut microbiome contributes to maintain homeostasis of host
2 metabolism¹. Disruption of this intricate system is associated with diseases such as obesity^{4,5} and
3 insulin resistance⁶. Metabolomics and the gut microbiome are strongly related, with microbes
4 producing many of the body's chemicals, hormones and vitamins⁷. The gut microbiome has been
5 reported to have an effect on circulating levels of several metabolites such as branched-chain amino
6 acids potentially causing insulin resistance⁶. However, despite the advances of next generation
7 sequencing platforms, which allow profiling of complex microbial communities using 16S
8 sequencing, annotation is sparse. Moreover, the microbiome only codes microbial possibilities
9 rather than their actual activity and cannot differentiate between alive and dead microbes⁸, nor
10 determine the transcriptional activity of the genes within each bacterial genome². Fecal
11 metabolomics, however, reports specifically on the metabolic interplay between the host, diet and
12 the gut microbiota³ and complements sequencing-based approaches with a functional readout of
13 the microbiome. Here we provide the first comprehensive description of the fecal metabolome in a
14 large population-based setting with the additional advantage of the twin model. We report (i) fecal
15 metabolites associations with age, gender and obesity; (ii) host genetic influences; and (iii) uni- and
16 multivariable dependencies with the gut microbiome.

17 We analyzed fecal samples of 786 predominantly female twins of the TwinsUK cohort, aged 65.2
18 (± 7.6), with an average BMI of 26.1 (± 4.7) (Supplementary Table 1) and we replicated our genetics
19 results in an independent sample of 230 individuals, aged 66.9 (± 8.6) with an average BMI of 27.2
20 (± 5.2). Untargeted metabolomics profiling of the participants' fecal samples was conducted by
21 Metabolon, Inc., using mass spectrometry, measuring a total of 1116 metabolites, 866 of them with
22 known chemical identity. Among the metabolites identified, 570 were common and detected in at
23 least 80% of the samples, while 345 were detected in at least 20% but in less than 80% of all samples
24 (Fig 1a). The latter were analyzed as dichotomous traits (present/absent in a sample) and
25 metabolites measured in less than 20% of the samples were discarded from further analysis. 647 of
26 the 1116 measured metabolites were not detected in blood samples of the same individuals profiled
27 on the same platform (Fig 1b). This suggests that the fecal metabolome provides complementary
28 information to blood metabolomics. We did not find significant associations between 915 fecal
29 metabolites and age after correcting for multiple testing. However, a multivariate partial least
30 squares discriminant analysis incorporating all the common 570 metabolites could distinguish the
31 oldest decile (>75 years) from the youngest decile (<56 years) of the study population (AUC=0.71,
32 $p=6.8 \times 10^{-6}$, Fig 2b) and one metabolite, phytanate, was significantly different between the oldest
33 and youngest deciles ($p=5.0 \times 10^{-3}$) (Fig 2a), suggesting non-linear associations between the fecal
34 metabolome and age in line with previous reports on the effects of age on the gut microbiome^{9,10}.
35 BMI was associated with eight metabolites at an FDR (Benjamini-Hochberg) of 5%: five fecal lipids,
36 including arachidonate (β [95% CI] = 0.13 [0.07:0.19], $p=1.1 \times 10^{-5}$), the hemoglobin metabolite

1 bilirubin (β [95% CI] = 0.13 [0.06:0.19], $p=8.9\times 10^{-5}$), and two unknown metabolites (Supplementary
2 Table 2). We then looked for associations with visceral fat mass, a measure of abdominal obesity,
3 correcting for BMI, and found a total of 102 statistically significant associations (FDR<5%, 13 passing
4 Bonferroni correction), which together explain 28.4% of the observed total variance of visceral fat
5 ($p<2.2\times 10^{-16}$) (Supplementary Table 2). In contrast, we find only 8 metabolites associated with BMI,
6 which is an imprecise measure of adiposity and measures overall mass without distinction between
7 lean and fat mass¹¹. However, the gut microbiome is known to play a major role in fatty acid
8 metabolism and adiposity which may be better reflected by visceral fat measures^{12,13}. Emerging
9 evidence also suggests a role of the intestinal microbiota in visceral development by interacting with
10 dietary components¹⁴. We have previously shown strong associations between visceral fat mass and
11 the gut microbiome composition^{15,16}. The much larger number of fecal metabolite associations with
12 visceral fat than with BMI are consistent with these findings and highlight the strong influence of
13 metabolic processes in the gut influencing abdominal adiposity.

14 Visceral fat-associated metabolites were significantly enriched for amino acids (43 metabolites,
15 enrichment $p<2\times 10^{-4}$) but also included 14 fatty acids, including arachidonate ($\beta=5.07$ [2.55:7.59], $p=$
16 8.2×10^{-5}), 8 nucleotides, 6 sugars and 6 vitamins. The strong association between the fecal
17 metabolome and central obesity confirms hypotheses on the involvement of microbial amino acid
18 metabolism in obesity and suggests new mechanisms, such as microbial vitamin B metabolism. We
19 have previously found several microbe families associated with lower visceral fat mass¹⁵ and
20 reduced weight gain in germ-free mice receiving human fecal transplants¹⁷. By analyzing the fecal
21 metabolome, we found the abundance of the same families to be strongly associated with
22 decreased abundance of amino-acids (see below), suggesting that their association with visceral fat
23 may be mediated by the availability of amino acids (Fig 3). This may be due to increased utilization or
24 decreased production of amino acids by these bacteria, or the result of more complex host-microbe
25 interactions.

26 The gut microbiome is heritable^{17,18} and we found a heritable variance component for 210 OTUs,
27 which explained on average 22.7% of the observed total variance. To test whether host genetic also
28 influences the fecal metabolome we first estimated its heritability, taking advantage of the twin
29 structure in our data (Fig 4) using structural equation modelling (148 MZ pairs, 155 DZ pairs). For 428
30 metabolites the best fitting model contained a heritable variance component (A), which explained
31 on average 17.9% ($\pm 9.7\%$) of the metabolite variation. Long chain fatty acid-containing metabolites,
32 such as 1-palmitoyl-2-arachidonoyl-GPC ($H^2=60.7\%$ [95% CI 43.4:78.0]) and stearyl carnitine
33 ($H^2=54.3\%$ [36.4:72.3]), were amongst the most heritable metabolites. For 279 metabolites,

1 including the coffee-metabolite 5-acetylamino-6-amino-3-methyluracil (C=30.3% [20.0:40.6]), the
2 best fitting model was the CE model, where the common environment component (C) explained on
3 average 14.8% ($\pm 8.1\%$) of the variance. For the remaining 208 metabolites, the best fitting model
4 was the E model where the entire variation of the metabolite is due to individual differences such as
5 the microbiome or individual diet (Supplementary Table 2). We found a significantly stronger
6 environmental effect on lipids than other metabolites (enrichment p -value $< 2 \times 10^{-4}$).

7 We subsequently conducted GWAS for the 428 metabolites with a heritable component
8 (Supplementary Table 3) and identified three metabolites (the amino-acid 3-phenylpropionate and
9 two lipids eicosapentaenoate and 3-hydroxyhexanoate) significantly associated with genetic loci
10 after correcting for multiple testing ($p < 1.2 \times 10^{-10} = 5 \times 10^{-8} / 428$) (Table 1, Fig 5a). We also tested for
11 genetic associations of metabolites ratios, which can be better proxies for chemical reactions than
12 single metabolites¹⁹. After correcting for 31,226 tested ratios we found the ratio of 5-acetylamino-6-
13 amino-3-methyluracil and 1,3-dimethylurate was associated with a locus on chromosome 8
14 (rs35246381, $p = 7.0 \times 10^{-21}$, p -gain = 7.5×10^9) (Table 1, Fig 5b). We replicated our GWAS results in an
15 independent sample of 230 individuals. Out of the 4 loci we tested, only the metabolite ratio of 5-
16 acetylamino-6-amino-3-methyluracil and 1,3-dimethylurate was significantly associated in the
17 replication cohort ($p = 3.6 \times 10^{-10}$; meta-analysis $p = 3.3 \times 10^{-36}$). The two metabolites 5-acetylamino-6-
18 amino-3-methyluracil and 1,3-dimethylurate are products of caffeine metabolism²⁰. The associated
19 locus at the *NAT2* gene codes for a N-acetyltransferase, which catalyzes the degradation of caffeine
20 metabolites²¹ (Supplementary Figure 3). Associations of this locus with other caffeine-metabolites
21 (1-methylxanthine, 4-acetamidobutanoate and 1-methylurate) have been previously observed in
22 blood²² and urine²³ and likely reflect efficiency of the degradation of caffeine. We then explored if
23 there were any eQTLs or other functional variants in strong LD with the top SNP. Although we found
24 three eQTLs (rs11996129, rs1112005, rs1799930) for *NAT2*²⁴, these are only in weak LD ($r^2 < 0.16$)
25 with rs35246381²⁵ and the associations between these SNPs and the metabolite ratio is weaker than
26 that of the top SNP ($p = 3.6 \times 10^{-10}$ vs $p = 9.4 \times 10^{-7}$). The tissues where the expression of *NAT2* is highest,
27 after liver, are in the jejunal and colonic mucosa, duodenum colon and small intestine²⁶ (see URLs).
28 This is consistent with polymorphisms in the *NAT2* gene being associated with the concentration of
29 caffeine derived metabolites in feces. We explored the relationship between caffeine and the fecal
30 metabolites 5-acetylamino-6-amino-3-methyluracil and 1,3-dimethylurate and find that their ratio is
31 positively correlated with both coffee intake and serum caffeine levels (Supplementary Figure 3).
32 These genetic association data illustrate how part of the complex metabolism of caffeine takes place
33 in the intestine before reaching the liver and that the links between the host genetic makeup and
34 xenobiotic concentrations can be captured by fecal metabolites. In addition to caffeine, the *NAT2*

1 enzyme is also involved in metabolism of various xenobiotics and is therefore related to variance in
2 drug response and toxicity²⁷. There is work showing that the composition of the gut microbiome
3 regulates xenobiotic enzymes, for instance the expression of *NAT2* is 1.5 higher in germ free animals
4 than in the large intestine of control animals²⁸. Taken together with our results these data fit with a
5 picture of xenobiotic metabolism being regulated jointly by host genetic variation and gut
6 microbiome composition.

7 We then investigated the extent to which the fecal metabolome reflect metabolic processes of the
8 gut microbiome. We regressed metabolite levels against microbial diversity (quantified by the
9 Shannon index), and found that 575 metabolites across all pathways showed a significant association
10 with microbial diversity at a FDR of 5%, with 347 passing a Bonferroni correction. We estimated the
11 proportion of variance in each metabolite explained by microbiome composition using the
12 unweighted UniFrac beta-diversity metric, a measure of overall phylogenetic dissimilarity between
13 individuals' microbiota²⁹. We found that gut microbial composition explained a significant proportion
14 of the observed variance of 710 metabolites, on average 67.7% ($\pm 18.8\%$) of the observed variance,
15 ranging from 22.1% for 1-linolenoylglycerol to 100% for several amino acids (Supplementary Table
16 2). Amongst others, the microbiome explained a significant proportion of the variance of the 8 BMI-
17 related and 101 of the visceral fat-related metabolites. Xenobiotics showed the strongest
18 associations with microbial composition (enrichment p-value $< 1 \times 10^{-4}$), which explained the entire
19 observed variance for some of them including the B-vitamins nicotinate and pantothenate.

20 To explore the associations of the fecal metabolome with gut microbes at a finer taxonomic
21 resolution we regressed each metabolite against the 581 most abundant operational taxonomic
22 units (OTUs), adjusting for potential confounding factors including Shannon diversity. We found
23 42,645 significant associations of 907 different metabolites with 579 different OTUs after adjusting
24 for multiple testing (FDR $<5\%$). We also calculated associations of fecal metabolites with collapsed
25 taxonomical levels, ranging from genus to phylum level (Supplementary Table 4). 264 metabolites
26 were only associated with microbes at the OTU level, with the remainder also associating with
27 broader taxonomic groupings.

28 Lastly, to investigate the connectivity of the fecal metabolome with microbes, we calculated a
29 Gaussian graphical model (GGM) combining 435 common metabolites with a known chemical
30 identity with 241 OTUs with complete taxonomy assignment to at least genus level. The resulting
31 model consists of 2553 independent associations, 1035 of them amongst metabolites, 946 amongst
32 microbes and 572 connecting metabolites and microbes (Supplementary Table 5 and Figure 4). All
33 but 9 variables form one connected component. We detect 19 clusters in the largest component, 9

1 of which contain both microbes and fecal metabolites and 10 consist of metabolites only.
2 Xenobiotics have higher node degrees ($p < 3 \times 10^{-4}$) and were more densely connected with OTUs
3 ($p < 2.4 \times 10^{-3}$). Our model demonstrates the high degree of interrelatedness between gut microbiome
4 and fecal metabolome, despite the very different technologies used.

5 In conclusion, although state of the art metagenomic sequencing allows quantitative and functional
6 annotation of species and microbial pathways³⁰, 16S sequencing data has limitations including the
7 lack of quantitative functional annotations. Fecal metabolomics provides a complimentary functional
8 readout of microbial metabolism as well as its interaction with host and environmental factors. We
9 have focused on the relationship between fecal metabolites and host and microbial genetics. Future
10 studies should further investigate the influence of environmental factors, particularly nutrition and
11 consider the influence of stool frequency/type on fecal metabolite measurements, as these are
12 known to be associated with fecal microbiome composition^{31,32}. The fecal metabolome can thus be
13 used as intermediate phenotype that promotes microbial effects on the host and vice-versa. Using
14 associations with obesity, we demonstrate that fecal metabolomics are a useful tool to complement
15 future genomic and microbiome studies.

1 **Figure Legends**

2 ***Figure 1. Number of measured fecal metabolites.***

3 1116 metabolites were detected in 786 fecal samples. (a) 570 of those were detected in at least 80%
4 of all samples and 345 were detected in less than 80% but more than 20% of all samples. The first
5 were analyzed continuously, while we dichotomized the latter in present/absent. 210 metabolites
6 that were present in less than 20% of the samples were excluded from further analysis. (b) 469
7 metabolites were observed in both, fecal and blood samples of the sample individuals, while 647
8 metabolites are unique to feces. 499 of these 647 metabolites were observed in at least 20% of the
9 fecal samples.

10 ***Figure 2. Association of the fecal metabolome with age.***

11 We compared the fecal metabolome between the oldest (>75 yrs., n=79) and youngest decile (<56
12 yrs., n=80) of the study population. (a) First, we investigated the age effect for all metabolites
13 individually using logistic regression models and found one metabolite, phytanate, significantly
14 different between the youngest and the oldest decile of our data. (b) Then, we fitted a multivariate
15 PLS-DA model to distinguish the older (red) from the younger (blue) group. We estimated the area
16 under the receiver operations curve (AUC) at 0.71 ($p=6.8 \times 10^{-6}$) in a 10-fold cross-validation.

17 ***Figure 3. Associations of fecal metabolites with gut microbiome correspond to microbial 18 effect on visceral fat.***

19 Visceral fat mass was significantly associated with 43 fecal amino acids (all positively) (n=647) and 32
20 OTUs (n=540) (6 positively in orange, 26 negatively in green). Red tiles indicate positive associations
21 between these metabolites and OTUs ($\beta > 0$) and blue tiles negative associations ($\beta < 0$); grey tiles
22 indicate non-significant associations (FDR > 5%). Microbial associations with fecal metabolites
23 correspond to their respective associations with visceral fat, indicating that the microbial metabolic
24 profile is more closely related to the host phenotype than taxonomy.

25 ***Figure 4. Intraclass correlation of fecal metabolites in MZ and DZ twins.***

26 The intraclass correlation coefficients (ICCs) were calculated from variance components of a one-
27 way analysis of variance separately for monozygotic (MZ, n=148 pairs) and dizygotic (DZ, n=155
28 pairs) twins for each metabolite. Positive values of their respective differences indicate more similar
29 metabolic profiles between MZ than DZ twins.

30 ***Figure 5. Host genetic influence on the fecal metabolome***

1 Genome-wide association studies were conducted for 428 heritable fecal metabolites and 31,226
 2 fecal metabolite ratios (n=739). P-values were calculated using the score test implemented in
 3 GEMMA. (a) The Manhattan plot illustrates the genetic associations of fecal metabolites in the
 4 discovery sample. The horizontal line indicates the Bonferroni cutoff of 1.2×10^{-10} . Three loci (red)
 5 pass the Bonferroni threshold. (b) The second Manhattan plot shows genetic associations with
 6 metabolite ratios in the discovery sample. The horizontal line indicates the Bonferroni cutoff of
 7 ($p < 1.6 \times 10^{-12}$). Two loci pass the threshold, however only the association with 1,3-dimethylurate / 5-
 8 acetylamino-6-amino-3-methyluracil ($p = 6.2 \times 10^{-21}$, red) passed filtering by p-gain ($p\text{-gain} > 8.9 \times 10^5$)
 9 and thus is considerably stronger than the association of each individual metabolite. Boxplots, QQ-
 10 plots, and regional association plots for each of the four loci are shown in Supplementary Figures 1,
 11 2 and Supplementary Data 1.

12 Tables

13 **Table 1. Genetic associations of fecal metabolites**

14 Three metabolites and one metabolite ratio significantly associated with genetic loci in the discovery
 15 cohort (n=739). We report their respective heritabilities (H^2), the associated variant along with its
 16 chromosomal position and the nearest gene, and the effect (\pm its standard error). P-values in the
 17 discovery and replication cohorts were calculated using the two-sided score test implemented in
 18 GEMMA and combined using fixed-effects inverse variance meta-analysis. The p-gain describes the
 19 strength of the association of the metabolite ratio relative to the associations of each individual
 20 metabolite.

Metabolite	H2	MAF	SNP	Gene	Discovery			Replication		Meta-Analysis	
					Effect	P	p-gain	Effect	P	Effect	P

22

1 **Online Methods**

2 ***Study population***

3 Study participants were 786 twins from the TwinsUK cohort. TwinsUK (a national twin registry) has
4 been recruited since 1992 through media campaigns and is representative of the population of the
5 UK in terms of life style³³. The study population is predominantly female (93.4% females), with an
6 average age of 65.2 (± 7.6) and an average of BMI of 26.1 (± 4.7). Ethical approval by St Thomas'
7 Hospital ethics committee; all participants provided informed written consent.

8 Results of the genome-wide association study were replicated in an independent set of 230
9 individuals (98.3% female) from the TwinsUK study, aged 66.9 (± 8.6) and an average BMI of 27.2
10 (± 5.2) (Supplementary Table 1).

11 ***Data collection***

12 Sample collection, DNA extraction, and sequencing of the samples within this study has been
13 described previously^{17,18}. Briefly, the fecal samples were collected, refrigerated and kept in ice packs
14 until they were frozen at -80°C (mostly within 24 hours from collection) before further processing. A
15 number of participants (15%) sent their samples by post.

16 ***Metabolomics profiling***

17 Metabolite concentrations were measured from fecal samples by Metabolon Inc., Durham, USA,
18 using an untargeted LC/MS platform as previously described^{22,34}.

19 **Sample preparation for global metabolomics**

20 Samples were stored at -80°C until processed. Sample preparation was carried out as described
21 previously³⁴ at Metabolon, Inc. Lyophilized feces samples were extracted at a constant per mass
22 basis. Briefly, recovery standards were added prior to the first step in the extraction process for
23 quality control purposes. To remove protein, dissociate small molecules bound to protein or trapped
24 in the precipitated protein matrix, and to recover chemically diverse metabolites, proteins were
25 precipitated with methanol under vigorous shaking for 2 min (Glen Mills Genogrinder 2000) followed
26 by centrifugation. The resulting extract was divided into five fractions: 1) acidic positive ion
27 conditions, chromatographically optimized for more hydrophilic compounds; 2) acidic positive ion
28 conditions, chromatographically optimized for more hydrophobic compounds; 3) basic negative ion
29 optimized conditions using a separate dedicated C18 column; 4) negative ionization following elution
30 from a HILIC column; 5) reserved for backup.

1 Three types of controls were analyzed in concert with the experimental samples: a pooled sample
2 generated from a small portion of each experimental sample of interest served as a technical
3 replicate throughout the platform run; extracted water samples served as process blanks; and a
4 cocktail of standards spiked into every analyzed sample allowed instrument performance
5 monitoring. Instrument variability was determined by calculating the median relative standard
6 deviation (RSD) for the standards that were added to each sample prior to injection into the mass
7 spectrometers (median RSDs were determined to be 5%; n = 31 standards). Overall process
8 variability was determined by calculating the median RSD for all endogenous metabolites (i.e., non-
9 instrument standards) present in 90% or more of the pooled technical replicate samples (median
10 RSD = 12%, n = 832 metabolites). Experimental samples and controls were randomized across the
11 platform run.

12 **Mass spectrometry analysis**

13 Extracts were subjected to UPLC-MS/MS³⁵. The chromatography was standardized and, once the
14 method was validated, no further changes were made. As part of Metabolon's general practice, all
15 columns were purchased from a single manufacturer's lot at the outset of experiments. All solvents
16 were similarly purchased in bulk from a single manufacturer's lot in sufficient quantity to complete
17 all related experiments. For each sample, vacuum-dried samples were dissolved in injection solvent
18 containing eight or more injection standards at fixed concentrations, depending on the platform.
19 The internal standards were used both to assure injection and chromatographic consistency.
20 Instruments were tuned and calibrated for mass resolution and mass accuracy daily.

21 All methods utilized a Waters ACQUITY UPLC and a Thermo Scientific Q-Exactive high
22 resolution/accurate mass spectrometer interfaced with a heated electrospray ionization (HESI-II)
23 source and Orbitrap mass analyzer operated at 35,000 mass resolution. The sample extract was
24 dried then reconstituted in solvents compatible to each of the four methods. Each reconstitution
25 solvent contained a series of standards at fixed concentrations to ensure injection and
26 chromatographic consistency. One aliquot was analyzed using acidic positive ion conditions,
27 chromatographically optimized for more hydrophilic compounds. In this method, the extract was
28 gradient eluted from a C18 column (Waters UPLC BEH C18-2.1x100 mm, 1.7 μ m) using water and
29 methanol, containing 0.05% perfluoropentanoic acid (PFPA) and 0.1% formic acid (FA). Another
30 aliquot was also analyzed using acidic positive ion conditions; however, it was chromatographically
31 optimized for more hydrophobic compounds. In this method, the extract was gradient eluted from
32 the same aforementioned C18 column using methanol, acetonitrile, water, 0.05% PFPA and 0.01%
33 FA and was operated at an overall higher organic content. Another aliquot was analyzed using basic

1 negative ion optimized conditions using a separate dedicated C18 column. The basic extracts were
2 gradient eluted from the column using methanol and water, however with 6.5mM ammonium
3 bicarbonate at pH 8. The fourth aliquot was analyzed via negative ionization following elution from a
4 HILIC column (Waters UPLC BEH Amide 2.1x150 mm, 1.7 μ m) using a gradient consisting of water
5 and acetonitrile with 10mM ammonium formate, pH 10.8. The MS analysis alternated between MS
6 and data-dependent MSn scans using dynamic exclusion. The scan range varied slightly between
7 methods but covered 80-1000 m/z.

8 **Compound identification, quantification, and data curation**

9 Metabolites were identified by automated comparison of the ion features in the experimental
10 samples to a reference library of chemical standard entries that included retention time, molecular
11 weight (m/z), preferred adducts, and in-source fragments as well as associated MS spectra and
12 curated by visual inspection for quality control using software developed at Metabolon^{35,36}.
13 Identification of known chemical entities is based on comparison to metabolomic library entries of
14 purified standards. Commercially available purified standard compounds have been acquired and
15 registered into LIMS for distribution to the various UPLC-MS/MS platforms for determination of their
16 detectable characteristics. Additional mass spectral entries have been created for structurally
17 unnamed biochemicals, which have been identified by virtue of their recurrent nature (both
18 chromatographic and mass spectral). These compounds have the potential to be identified by future
19 acquisition of a matching purified standard or by classical structural analysis. Peaks were quantified
20 using area-under-the-curve. Raw area counts for each metabolite in each sample were normalized to
21 correct for variation resulting from instrument inter-day tuning differences by the median value for
22 each run-day, therefore, setting the medians to 1.0 for each run. This preserved variation between
23 samples but allowed metabolites of widely different raw peak areas to be compared on a similar
24 graphical scale.

25 A total of 1116 different metabolites were measured in the 786 fecal samples, of which 210 were
26 observed in less than 20% of the samples and thus excluded from further analysis due to lack of
27 power. 345 metabolites were observed in more than 20% but less than 80% of the samples and were
28 thus analyzed qualitatively as dichotomous traits (observed in a sample vs. not observed). The
29 remaining 570 metabolites, which were observed in at least 80% of all samples, were scaled by run-
30 day medians, log-transformed and scaled to uniform mean 0 and standard deviation 1 and analyzed
31 quantitatively (Fig 1). Metabolite ratios were calculated from the run-day median normalized
32 metabolite levels and subsequently log-transformed and scaled to a mean of 0 and standard
33 deviation of 1.

1 We analyzed effects of sample storage time (i) in the fridge before samples were frozen and (ii) in
2 the freezer before being further analyzed. To this end we regressed metabolite concentrations
3 against storage times. After correcting for multiple testing, we found significant storage effects on 7
4 metabolites (FDR < 0.05) (Supplementary Figure 5). We, thus, corrected all further analyses for both
5 storage time in the fridge and freezer, to avoid spurious results. Despite correcting all models for the
6 storage time, we cannot ultimately eliminate a potential confounding effect due to storage time and
7 future studies should investigate its influence on fecal metabolites.

8 ***Microbial sequencing***

9 16S rRNA was extracted from fecal samples, PCR amplified, barcoded per sample and sequenced
10 using the Illumina MiSeq, as previously described¹⁸. DNA was isolated from the samples using the
11 PowerSoil kit. The V4 region of bacterial 16S rRNA gene sequences was PCR amplified using the 515F
12 and 806R primers³⁷. Reads were barcoded per sample and combined for multiplexed sequencing
13 using the Illumina MiSeq to generate 250bp paired-end reads. Paired-end reads were merged with a
14 minimum overlap of 200nt using fastq join within QIIME, which was also used to de-multiplex the
15 sequence data.

16 Pre-processing of sequences and their clustering to operational taxonomic units followed the
17 Sumaclus de novo approach as previously described for a subset of samples from³⁸. In brief, 16S
18 sequence reads for all samples were filtered to remove chimeric sequences produced during PCR,
19 using USEARCH for chimera identification³⁹. Remaining reads were then collapsed to operational
20 taxonomic units (OTUs) using the Sumaclus algorithm for de novo clustering in QIIME 1.9.0, this
21 method selected as de novo OTUs more accurately group reads at the 97% level⁴⁰, and Sumaclus
22 was the one of the best performing greedy clustering algorithms in previous comparisons³⁸.
23 Taxonomy was assigned to OTUs by alignment of representative sequences to the Greengenes 13_8
24 database with a 97% similarity threshold using UCLUST.

25 De novo clustering across all samples within the TwinsUK cohort produced ~300,000 OTUs after
26 singleton removal; however, the majority of these were of low abundance and found in very few
27 samples (table density 0.002). The OTU table was subset, discarding samples with fewer than 10,000
28 reads and OTUs that were not found in at least 25% of these samples. This resulted in a table of 581
29 OTUs (table density 0.547) (Supplementary Table 7). OTU counts were converted to relative
30 abundances (over all reads in each sample), a pseudo count of 10^{-6} was added to account for zero
31 counts, and the abundances were log transformed. The transformed abundances were then used as
32 the response in models with sequencing run, sequencing depth, individual who extracted the DNA,
33 individual who loaded the DNA and sample collection method as technical covariates. The residuals

1 of these models were then used in downstream analysis of OTU abundances. The same
2 normalization and control for technical effects was also carried out on taxonomic abundances
3 collapsed at each taxonomic level. Collapsed taxonomies included counts from all OTUs. Shannon
4 alpha diversity was also calculated from the complete OTU table. Each sample was rarefied to a
5 depth of 10,000 reads 50 times. Diversity metrics were calculated for each sample in each table and
6 the mean across all tables taken as the final measure. Beta diversity was calculated from all OTUs
7 excluding singletons using the unweighted UniFrac algorithm²⁹.

8 ***Visceral fat measurements***

9 Measurements of whole body composition were performed using the DXA fan-beam technology
10 (Hologic QDR; Hologic, Inc., Waltham, MA, USA) as previously described⁴¹. Briefly, subjects were
11 positioned in a standardized manner, in a supine position with the clothes removed and wearing a
12 gown. The DXA machine was calibrated on a daily basis using a spine phantom and on a weekly basis
13 using a step phantom, as suggested by the manufacturer. The scans were analyzed using the QDR
14 System Software Version 12.6.

15 Regions of interest were defined manually by the same operator following the SOP, which was
16 derived from the manufacturer's guidelines. The lower horizontal margins were placed above the
17 pelvis, just above the iliac crest, while the upper horizontal margins were placed at the half of the
18 distance between the acromions and the iliac crest. The vertical margins were adjusted just at the
19 external borders of the body so that all the soft tissue was included.

20 This DXA-based measurement of visceral fat has been validated against VF measured by CT scan and
21 shown to be reliable and reproducible⁴².

22 ***Statistical analysis***

23 To assess the influence of age and gender on metabolite measurements, we regressed all
24 metabolites against age and gender, correcting for family structure as random intercept using the R
25 package lme4⁴³. Moreover, we calculated linear and logistic regression models, respectively, to
26 assess the relationship of the fecal metabolome with obesity, measured as BMI and visceral fat mass
27 (measured by double X-ray absorptiometry), respectively adjusting for age, sex, storage time and
28 family as random intercept. Visceral fat measurements were available for 647 individuals. The
29 following regression models were used:

30 a) Associations of metabolites with age and gender

31 Metabolite ~ **age** + **gender** + storage time (fridge) + storage time (freezer) + (1 |family)

32 b) Associations with BMI

1 **BMI** ~ Metabolite + age + sex + storage time (fridge) + storage time (freezer) + (1 | family)

2 c) Associations with visceral fat mass

3 **visceral fat** ~ Metabolite + age + sex + BMI + height + height² + storage time (fridge) +
4 storage time (freezer) + (1 | family)

5 d) Associations with microbial alpha diversity

6 Metabolite ~ **microbiome diversity** + age + sex + BMI + storage time (fridge) + storage time
7 (freezer) + (1 | family)

8 e) Associations with OTUs and taxa

9 Metabolite ~ **microbe (OTU/taxa)** + microbiome diversity + age + sex + BMI + storage time
10 (fridge) + storage time (freezer) + (1 | family)

11 **Partial Least Squares Discriminant Analysis**

12 We used a partial least squares discriminant analysis (PLD-DA) to investigate global differences
13 between the metabolic profiles of the youngest and oldest decile of our study population. To this
14 end, all missing values were imputed using the mice package⁴⁴ and metabolite levels were adjusted
15 for storage times and family structure by linear mixed models. Residuals of these models were then
16 used to train a PLSDA model as implemented in the mixOmics package⁴⁵. The predictive performance
17 was assessed using a 10-fold cross validation.

18 **Heritability analysis**

19 We used structural equation modelling to estimate the genetic (A), the common environment (C)
20 and the unique environment (E) components of the total variance for each metabolite⁴⁶. To this end
21 we used the R package mets (version 1.1.1) to fit maximum-likelihood models, adjusting for age and
22 sex and storage time. For each metabolite we fitted four models, estimating (1) A, C and E
23 components (2) A and E components, (3) C and E components and (4) E component only. The best
24 model was selected by minimizing the Akaike Information Criterion (AIC). In case of dichotomous
25 metabolite abundances, a liability-threshold model was fitted using the bptwin function of the mets
26 package. Additionally, intraclass correlation coefficients (ICCs) were calculated from variance
27 components of a one-way analysis of variance for MZ and DZ twins individually, using the ICC
28 package⁴⁷.

29 **Genome-wide association study**

30 Genetic variation was measured using whole genome sequencing, as previously described⁴⁸. In brief,
31 samples were sequenced using the Illumina HiSeqX sequencer with 150 base paired reads. Reads
32 were then mapped to hg38 genome using ISIS Analysis Software (v. 2.5.26.13; Illumina) and missing
33 genotypes were filled in with reference homozygous calls⁴⁹. Genomes with a ratio of heterozygous to

1 homozygous variants higher than 2.5 were excluded leaving 739 individuals for further analysis. A
2 cohort-based high confidence region of the genome was constructed by concatenating positions
3 with greater than 90% "PASS" call rate using data from 3 sets of 100 randomly selected genomes.
4 Variants outside of the high confidence region and duplicated variants were removed. We moreover
5 excluded 273,355 variants with Hardy-Weinberg $p < 10^{-6}$, calculated from 420 unrelated individuals,
6 leaving 8,208,502 biallelic SNPs and 1,408,051 InDels with minor allele frequency higher than 1% for
7 further analysis.

8 We fitted linear mixed models to test for associations of heritable fecal metabolites with genetic
9 variants, correcting for age, sex, storage time using GEMMA⁵⁰ incorporating data from 739
10 individuals with fecal metabolomics and sequencing data. The twin structure of our data was taken
11 into account by adjusting for the family relatedness using the sample kinship matrix. The score test
12 implemented in GEMMA was used to assess significance of the associations. We considered
13 metabolite-associations with a p-value lower than 1.2×10^{-10} significant, which corresponds to a
14 genome-wide significance cut-off of 5.0×10^{-8} , corrected for 428 tested metabolites. Additionally, we
15 tested for genetic associations with all pairwise metabolite ratios of fecal metabolites with known
16 chemical identity and a heritable variance component. We used the p-gain statistic to assess
17 independence of the single metabolites¹⁹. The p-gain is defined as the minimal p-value of the
18 associations of either of the single metabolites divided by the p-value of the metabolite ratio. A high
19 p-gain statistic indicates that the ratio carries additional information compared to individual
20 metabolites. We considered metabolite ratios with $p < 1.6 \times 10^{-12}$ ($= 5 \times 10^{-8} / 31,226$ metabolite ratios)
21 and $p\text{-gain} > 3.1 \times 10^5$ ($= 10 \times 31,226$ metabolite ratios) significant.

22 Four genome-wide significant associations were replicated in 230 individuals of the TwinsUK study,
23 adjusting for the same confounding factors. Results of discovery and replication were combined
24 using fixed-effects inverse variance meta-analysis.

25 **Associations of the fecal metabolome with the gut microbiome**

26 To assess associations of the fecal metabolome with the gut microbiome, we first regressed
27 metabolite concentrations against the Shannon alpha diversity, adjusting for age, sex, BMI, storage
28 time and family structure using 644 individuals with both fecal metabolomics and 16S sequencing
29 data available.

30 We then estimated the proportions of variance of each metabolite explained by the microbiome by
31 regressing the fecal metabolite concentration against the microbial beta-diversity. This technique is
32 commonly used to estimate heritability from genetic kinship matrices^{51,52}. To this end we calculated

1 a restricted maximum likelihood model (REML), regressing the metabolite level against the microbial
2 similarity, adjusting for age, sex, BMI and the storage time in fridge and freezer and technical
3 covariates (sequencing run, sequencing depth, individual who extracted the DNA, individual who
4 loaded the DNA and sample collection method) using the R package regress. The proportion of
5 variance explained by microbial similarity (M2) and its standard error were calculated from the
6 variance components using the R package gap⁵³ and p-values were calculated from the ratio of M2
7 over its standard error.

8 Next, we aimed to identify microbes and taxonomical units that are associated with metabolite
9 levels. To this end we regressed 581 inverse normalized operational taxonomic units (OTUs) against
10 all 915 metabolites, adjusting for age, sex, BMI, sample storage times, family structure and the alpha
11 diversity. Benjamini-Hochberg correction was applied to account for multiple testing. We further
12 calculated associations at different taxonomical units, from genus to phylum level.

13 Lastly, to assess multivariate dependencies between the fecal metabolome and the microbiome, we
14 inferred a graphical model combining 423 metabolites with known chemical identity that were
15 observed in at least 80% of the samples with 241 OTUs that were assigned complete taxonomy at
16 least to the genus level. Sparse graphical models were inferred using the GeneNet package⁵⁴ and
17 edges with false discovery rate < 0.05 were included in the model. We used the Fruchterman-
18 Reingold algorithm⁵⁵ to determine an unbiased graph layout and identified network modules by
19 optimizing the modularity score as implemented in the igraph package⁵⁶.

20 **Pathway enrichment**

21 We used pathway annotation as provided by Metabolon for pathway enrichment using the page
22 algorithm. Enrichment p-values were estimated using permutation tests with 10,000 random
23 permutations as implemented in the R-package piano⁵⁷.

24 **Graphical model inference**

25 To assess multivariate dependencies between the fecal metabolome and the microbiome we
26 inferred a graphical model combining 435 metabolites with known chemical identity that were
27 observed in at least 80% of the samples with 241 OTUs that were annotated at least down to the
28 genus level. To obtain a full data matrix we first imputed missing metabolite levels using mice⁴⁴. A
29 sparse graphical models was inferred using the GeneNet algorithm⁵⁴ selecting edges with FDR < 0.05.
30 We used the Fruchterman-Reingold algorithm⁵⁵ to determine an unbiased graph layout and
31 identified network modules by optimizing the modularity score as implemented in the igraph
32 package⁵⁶. For visualization purposes, we collapsed all metabolites of the same pathway to one

1 node, which was connected to all neighbors of all its members. Microbes were collapsed by family.
2 For both the full and the collapsed network, we calculated several centrality measures of nodes,
3 including node degrees, as number of neighbors, clustering coefficients, as proportion of neighbors
4 that are connected, and betweenness centralities, as proportion of shortest paths incorporating a
5 node.

6 **Data availability**

7 16S sequencing data used for this study is deposited in the European Nucleotide Archive
8 (ERP015317). All other TwinsUK data are available upon request on the department website
9 (<http://www.twinsuk.ac.uk/data-access/accessmanagement/>).
